In spite of these powerful currents, there still remained the hard core of traditional elementarism in the Hull school of associationism, in the conventional psychophysical work on sensory processes, and in the item-reliability approach of the psychometrician. For some psychologists no assimilation seemed possible between the older laboratory psychology and the later concern with complex social-psychological problems. Indeed, the conflict threatened to split psychology into two separate branches, one allied to biology and the other allied to the social sciences. Harvard university decided upon this solution and in 1946 organized a new department of social relations, bringing together social and clinical psychology with sociology and social anthropology, while physiological psychology remained by itself as one of the natural science departments. Most psychologists, however, opposed this schism and believed an integration was possible. The desire to preserve psychology as a unified science, and at the same time not restrict its many interests, was implemented formally in the reorganization of the American Psychological association in 1944. The new organization, a federated structure with divisions set up according to functional interests, maintained considerable local autonomy for the various divisions, and a central governing body of divisional representatives. Thus the common ground as well as the specialized interests of the many branches of psychology were to be served. The new organization, moreover, devoted itself not only to the advancement of psychology as science but to its advancement as a profession and as a means of promoting human welfare.

In spite of the diversity of interests among psychologists, it should be noted that the trend away from elementarism made possible a common language and a common set of concepts. Memory, learning and perception as studied by modern field systems yielded findings not only of pertinence to social psychology but findings capable of formulation in the same conceptual language. Perception of the physical world, for example, in terms of organized wholes and of subjective structure supplying the lack of objective structure also applied to the individual's perception of social situations.

The Society for the Psychological Study of Social Issues, founded in 1936, stimulated and hastened the development of the new trends. Its main purpose was to further research in social psychology and to make research findings available for social welfare. By its interest in problems of the real social world it counteracted atomistic and ivory-tower tendencies in social psychology. Its three yearbooks, *Industrial Conflict*, *a Psychological Interpretation*, *Civilian Morale* and *Human Nature and Enduring Peace*, were co-operative research undertakings of large groups of workers

and were integrated symposia of psychological research and thinking on all-important contemporary issues.

Specific Advances

Against the general background of a broadening methodology and subject matter there were many specific advances. Some of the more significant developments were the following:

Heredity vs. Environment.—The nature-nurture controversy was resolved in fair measure by studies showing the way in which inherited and environmental factors interact. The old behaviouristic movement with its agnosticism of inherited doctrines went to the extreme of neglecting even the biochemical constitution of the individual. On the other hand, the heredity school had an oversimplified view of human character as the mere unfolding of traits carried by the genes. Research indicated, however, that the dynamics of behaviour determination are complex. The effect of heredity is indirect and is mediated by constitutional factors (the physical and chemical make-up of the individual) which in turn are mediated in their influence by learning. The genes help to determine, but are not synonymous with constitutional factors, since they operate not in a vacuum but in a physical environment of varying nutritive conditions, vitamins, temperature electrical gradients, etc. This interaction between the genes and the physical and chemical materials of the environment results in a glandular, nervous and physical constitution which is a determinant of behaviour, but more in a limiting than a direct fashion. For example, young children differ constitutionally in sensitivity of receptors, in autonomic threshold, in size of glands. Hence one child may develop a trait of emotionality more readily than another.

But the kind of emotionality and the degree to which it is developed is mediated through the nature of his experiences.

Thus some correlation exists between physical and glandular constitution and temperamental aspects of personality, though the correlation will never be a constant for all groups under all conditions. S. S. Stevens and W. S. Sheldon in an extensive investigation of the problem empirically derived three measures of physical type: (a) endomorphy, greater or less prominence of the abdominal region, or digestive viscera, (b) mesomorphy, greater or less prominence of bone, muscle and connective tissue and (c) ectomorphy, large surface in relation to mass; long delicate bones. Two hundred individuals were scored on these three dimensions and were also given a battery of personality tests. Clusters of personality traits, obtained through factor analysis, were found to be related to body types. Ectomorphy was definitely associated with this personality pattern: overly fast reactions, inhibited social address, restraint in posture, poor sleep habits, vocal restraint, youthful intentness and need of solitude when troubled.

Endomorphy accompanied this cluster: love of comfort, relaxation, pleasure in digestion, greed for affection and approval, deep sleep and the need for people when troubled.

Studies of animals also demonstrated the relation between temperament and constitution. C. Hall employed behavioural tests to determine degree of emotionality and fearlessness in rats. By controlled breeding, strains of fearless and emotional rats were obtained. Anatomical analysis of the glandular constitution revealed larger adrenal, thyroid and pituitary glands in the emotional than in the fearless animals.

Constitutional factors determine capacities and aptitudes but they do not set in absolute fashion a rigid degree of ability. Rather they mark the limits of a possible range of behaviour. Thus the skills and talents of most people can be appreciably improved by training, but the musical moron can never be made into a musical genius. While the I.Q. is relatively stable, a number of studies showed that it can be varied under changing environmental conditions. Foster children tend to change I.Q. in the direction of the level of the foster home. And Irving Lorge compared a group of boys who left school at the end of the eighth grade with a group matched in I.Q. who went on to complete college. A retest of I.Q. 20 years after completion of grammar school showed that the college group averaged 15 points higher than the noncollege group.

Training and experience are not as important for some elementary functions and at as early ages as was assumed by environmentalists. Wayne Dennis in a study of Hopi children found that those restricted in activity by being bundled to a stiff board in orthodox Hopi fashion walked as early as those who had been reared like white children without binding. Early activities of motor manipulation and co-ordination are more dependent upon maturation of biological factors than upon learning. The heavy emphasis of some Freudians upon the significance of breast-feeding and the early libidinal treatment of the infant for later personality development lacked experimental confirmation. Physiological rather than psychological forces are important in the early months of life.

Physiology.—Knowledge of the physiological basis of behaviour steadily increased through research involving destruction of nervous tissue and experiments with the effects of drugs and hormones on behaviour. Evidence accumulated, definitely confirming older views, that the function of the frontal lobes of the cerebral cortex is one of intellectual synthesis and elaboration and of inhibition of subcortical centres. Loss of the frontal lobes not only impairs the symbolic processes, but results in freer emotional expression. Work on both human patients and lower animals emphasized the importance of the frontal cortical areas for planning of activity, for anticipation, and for all organized patterns with a future reference. Prefrontal lobotomies on neurotics and psychotics had some measure of success. Though patients show a more ready emotionality after the operation, they also lose their deep-lying anxieties and other neurotic symptoms.

Laterality (the preference in the use of the right hand over the left, or the dominance of one eye over the other) is not a unitary system neurologically. Sectioning of the corpus collosum can affect some functions involving sidedness but not others.

Records on human patients with brain lesions, who sleep inordinately, had long suggested a "sleep centre" in the hypothalamic-mesencephalic region of the brain. Experimental tests were made, therefore, on monkeys by destroying various subcortical centres and observing subsequent behaviour. In cases of injury to the hypothalamus and mesencephalon, somnolence generally ensued. In his phylogenetic theory of sleep O. Kleitman localized a wakefulness centre in this part of the brain. According to this theory, the wakefulness centre would ordinarily follow a shorter rhythm of activity and rest as in the lower animals, if it were not for the activity of the cortex. A high degree of cortical functioning activates the lower wakefulness centre. In turn the centre acts as a priming mechanism to keep the cortex on the job. During sleeping or waking the normal vegetative activities of the organism are maintained, but the wakefulness centre is necessary

to sustain the higher integrative cortical process.

Attempts to establish a biochemical basis for the functional psychoses were numerous but without definitive results. Schizophrenia, with its progressive deterioration, had long impressed clinicians as an organic condition. Some studies did report a relation between specific toxins and schizophrenia, and R. Lemere as a result of his electroencephalography investigations regarded a low-energy cortex as the origin of the disease. The conflicting evidence and the long history of failure in this type of research suggested that the functional psychoses are not organically based, in the sense of arising out of specific toxins or specific physiological conditions, but are functions of total nervous organization. This theory did not reject the possibility of a re-enforcing biochemical specific as one aspect of the disordered condition which helps to set up a strong circular process of malfunctioning. Much had been claimed for insulin and other chemical treatment of mental breakdown—especially if combined with psychotherapy. By changing body chemistry and thus breaking up the circular re-enforcing processes, the drug treatment may give psychotherapy the necessary entering wedge for re-education. Shock treatment may also help recovery by breaking up the neural organization of the poor adjustment of the personality. There was some evidence of memory impairment for recent events attributable to insulin or electric shock. After the convulsions and coma, the personality must reintegrate and may fall back upon earlier and more wholesome habits of response than the recent schizophrenic pattern. (See also BIOCHEMISTRY; PHYSIOLOGY; PSYCHIATRY.)

Personality Tests.—Projective methods for the evaluation of personality came into their own within the decade 1937–46. Paper-and-pencil tests of character and temperament were atomistic and superficial, though they had still their uses for rough group-screening. The projective test was a clinical development. Instead of an inventory of more or less direct questions with limited and fixed alternative answers, it presented unstructured and incomplete situations. In responding to these situations, the subject "projected" into his answers his own frame of reference, his own motives, his own conflicts. The most famous projective instrument was the Rorschach ink blot test. Coloured blots of various sizes and shapes were presented on cards to the subject for his interpretation. Another widely used device was the Murray thematic apperception test, a series of pictures which the respondent was asked to use for plots of his own construction. These tests were employed extensively in clinical psychology for diagnosis, in developmental psychology, in vocational guidance and in personality research. The literature in this field covered hundreds of titles.

For a long period the projective tests were handicapped by lack of demonstrable evidence to support the ambitious claims sometimes made for them. In its very nature of seeking qualitative and uncontrolled responses, the test did not seem to lend itself to rigorous standardization and statistical checks. But by abandoning the traditional item-validity approach and seeking for quantitative checks in broader dimensions, the reliability and validity of the projective methods were established. In one study Ruth Munroe gave the Rorschach to a group of university freshmen, wrote "blind" personality descriptions on the basis of the test results and asked teachers who knew the subjects to match the descriptions with the names of the students. The sketches were matched perfectly. In a

further experiment predictions of academic success were made on the basis of Rorschach protocols and were found to be radically wrong in only 4 out of 178 cases. Other predictions of adjustment correlated .65 with a teacher rating of adjustment. Against the objective record of actual behaviour, including referral to a psychiatrist, academic failure and problem behaviour observed by teachers, the Rorschach predictions also fared well. The Bernreuter paper-and-pencil inventory, in contrast, completely missed some of the most seriously maladjusted students.

Similarly, the thematic apperception test was validated at Worcester State hospital. The test was administered to 40 patients unknown to the experimenter, who then wrote thumbnail sketches of their personalities, made I.Q. estimates and prediction as to disease classification. The sketches were successfully matched with the identities of patients, and the predictive estimates were accurate in more than three-fourths of the cases.

The significance of the validation of projective methods was far reaching. It illustrated the possibilities of bringing into the scientific realm the rich qualitative materials generally regarded as belonging to the intuitive, the aesthetic and the practical worlds. The projective technique was extended to the field of children's play activities. Children's use of play materials afforded insight into their personalities, their way of thinking and of feeling.

Social Psychology.—Social psychology had a mushroom growth. Until the middle 1930s Allport's classic text of 1924, with its emphasis upon the elementary functions, remained the standard work. After 1935 no less than eight major texts, and many research monographs and theoretical volumes carried the psychological approach into the most complex social issues. One aspect of this growth was the expansion into those areas of social science where the problems were regarded as problems of human behaviour, notably the formation and measurement of public opinion, the analysis of propaganda and its effects, the study of labour-management relations and industrial conflict, and perhaps most significant, the investigation of the dynamics of culture. In fact, the unity achieved at Harvard in the formal merger of social psychology and social anthropology reflected the co-operative research and the cultural diffusion and borrowing between anthropology and psychology. Anthropologists turned to psychological findings for an understanding of motivation. At the Yale Institute of Human Relations part of the training of anthropological field workers was thorough knowledge of the techniques of psychoanalysis. As a consequence the ethnological field-account of primitive peoples began to give attention to the personality development and motivation of its characters.

In turn social psychology eagerly seized upon comparative materials from various cultures showing both the similarities and differences in human reactions to basic stimulus-situations. The ethnological contributions greatly aided the distinction between the phenotypical, or variable surface manifestation, and the genotypical, or deep-lying principle. Too often in the past, the practice had been to regard any observed phenomenon in an individual culture as a fundamental trait of human nature. For example, psychoses and psychoneuroses had often been defined in terms of symptoms such as delusions of persecution or trance-like states. Anthropological accounts showed, however, that in some cultures these manifestations are the socially approved way of behaving, and are not indications

of abnormality. Hence in modern psychology it became necessary to define abnormality at the genotypical level, *i.e.*, the nature and degree of internal conflict and resulting personality disorganization.

The work of A. Kardiner and his group, reported in the two volumes *Individual and His Society* and *Psychological Frontiers of Society*, illustrated the possible fusion of anthropology and psychology. This account of psychodynamics was the definitive answer to the static conception of social behaviour held by the extreme culture determinists and by the extreme nativists. The one group saw human beings as the mere carriers of social norms, each generation automatically acquiring the social norms of the preceding generation much as their opponents, the nativists, saw social behaviour as the reflection of inherited traits. Both the advocates of social inheritance and the adherents to biological inheritance were alike in a point of view that could explain neither social change nor even social stability. Kardiner, however, put major attention upon the socialization process as the important dynamic in personality development and subsequent social behaviour. The way in which the many specifics of early disciplines and sanctions are applied in relation to the particular needs of the growing child, the impact of maternal care, sibling interactions, paternal dominance or absence—all establish action systems which in their interactions yield basic personality. Projective systems arise out of the early action systems and determine religion, folklore and the arts. Reality systems supplement the projective systems and deal with explanations of the outer world, ways of dealing with it, or conventionalized means of getting along with others. This developmental approach grows out of a careful analysis of several primitive societies.

While Kardiner and the Yale group were working on fundamental psychodynamics in comparative cultural studies, specific techniques for field research employing quantitative controls evolved rapidly in the war years in opinion and attitude surveys. These techniques gave promise of revolutionizing social psychology. They provided a way over a main stumbling block to scientific progress in the social field—the problem of the measurement or control of the significant forces affecting social action. The bulk of social science observations had been prescientific. These observations may or may not have been accurate, for they were not reported in a manner allowing for verification. And since there was no measure of the extent of their accuracy, no generalizing functions or predictions could be derived from them. For example, Willard W. Waller's superior book, *The Veteran Comes Back* (1944) gave excellent insights into the problems of returning servicemen and the mutual adjustment between veteran and civilian. But with no quantification of these observations, no knowledge of the gravity or extent of the anticipated maladjustment was possible.

Opinion polls had demonstrated that even rough sampling techniques gave accurate predictions of voting behaviour from very small samples. The census bureau and the division of program surveys of the U.S. department of agriculture refined sampling procedures so that a study of a small fraction of the population would give accurate estimates of the number of people redeeming their war bonds within a given period, the prospective buying behaviour of different income groups for various commodities, or the morale of workers in a given type of industrial plant, etc. By making the reactions of the individual the standard unit, behaviour variables could be reliably identified and measured. But it was also important that the variables measured be truly significant. The ready quantification

according to a precoded set of simple alternatives would often miss human motives, conflicts, aspirations and ideology. Two techniques were devised and successfully used for an exploration and measurement of significant variables—the nondirective depth interview and the subsequent coding of the rich interview materials. The depth interview conducted by a skilled, trained field worker emphasized rapport with the respondent, who was encouraged to talk in narrative style on the whole subject under discussion. This topic was set in as broad a frame as possible, and as the respondent proceeded, the questions gradually narrowed the discussion to specific phases of the problem. The recorded ideas and feelings from such interviews were later examined by expert coders, who set up quantitative ratings and dimensions according to the nature of the interview material. These ratings and dimensions were checked independently by a number of coders for reliability and revised until reliable measures were obtained. With these techniques and with adequate psychological knowledge for devising a study with experimental design, the problems capable of scientific attack in the field of human relationships became almost limitless. (See also PUBLIC OPINION SURVEYS.)

Another less crucial stumbling block to a scientific social psychology was the inability to control and manipulate the social world as a physicist manipulates his materials. Actually, however, social change occurs frequently enough so that adequate field studies, strategically placed, could go far to remedy this weakness. A. Leighton, to take one instance, carefully observed the social upheaval in a Japanese relocation centre housing Nisei, Issei and Kibei groups. In this situation the dominant position of the U.S.-born Japanese, the Nisei, over the older generation of Japanese was reversed. In spite of their familiarity with U.S. ways they, too, were outcasts and the older-generation Japanese resumed the role that their culture prescribed for them. Here then was a natural social situation with something of the setting of an experiment. Moreover, action programs could be experimentally planned with accompanying research evaluation. The Commission on Community Interrelations embarked upon a program of bringing about better relations in the community among different religious and racial groups. In formulating its plans, it provided for constant checks on the effectiveness of various procedures for modifying social behaviour. Its work showed the importance of effecting change not through exhortation or propaganda but through active role-playing by community members themselves. If the community could be encouraged to study the problem itself and to work out its own program, more was accomplished than by the usual informational and educational approach. This further extended the accepted psychological principle of active participation and role-taking as the important factor in behaviour modification.

War Activities

The United States made more use of psychologists in World War II than any other nation. Though the very term "military psychology" was associated with Germany, German psychologists were utilized largely in the selection of officers and key military personnel. Clinical psychology was in good part neglected, partly because the official military attitude was to deny the existence of psychogenic difficulties in the German soldier. Nor were social psychologists employed for the evaluation of morale or propaganda. Moreover, the selection program was discontinued in the German army and air forces in the middle of the war. This was due in part to weaknesses of quantitative

techniques in German psychology and the failure to obtain validating data for the tests. But another significant reason was the opposition by both the Prussian officer group and the Nazi party to democratic selection on the basis of aptitude and ability. The Prussian officers wanted candidates for officers to come from the old Prussian families and the nazis favoured preference for the boys who had belonged to the Hitler youth groups.

Even before the entry of the U.S. into the war the Emergency Committee in Psychology of the National Research Council started to mobilize psychological knowledge having to do with problems of human engineering in times of crisis and war. Bibliographical surveys of various aspects of military psychology appeared in the *Psychological Bulletin* of June 1941. The emergency committee continued throughout the war as a top advisory group for army personnel procedures. Under its direction, two volumes were prepared for the use of the army: *Psychology for the Fighting Man*, a popular condensation and application of psychological facts important for the serviceman, and *Psychology for the Returning Serviceman*, a summary for the returning veteran of psychological knowledge about his postwar problems. But the bulk of war research was carried on directly by the operating agencies interested in the results—the army, navy, the OSS and OWI. Research projects, contracted out to universities and colleges, cleared for the most part through the Applied Panel of the National Defense Research Council or some other agency of the Office of Scientific Research and Development.

U.S. Army Ground Forces.—The main uses of psychology in the U.S. army were in the classification and selection of personnel, in clinical problems of maladjustment, and in morale measurement. By far the most attention was given to the selection and classification program. The most neglected areas were in training, especially of leaders, and in the implementation of morale research.

Personnel procedures, including all testing, selection, assignment and related research were the responsibility of the Adjutant General's office, which was advised by a committee of prominent psychometricians under the chairmanship of Walter Bingham. Actual administration of personnel procedures was handled by the classification and replacement branch, A.G.O. Most of the officers administering the program in the field were psychologists and personnel technicians, especially trained for their tasks at the Adjutant General's school, established in 1941 at Fort Washington, Md. The central direction of the program came from the personnel research section of the classification branch, which as the operating agency of the A.G.O. was charged with the responsibility for the development, construction, validation and standardization of all personnel screening tests and interviewing techniques in the army with the exception of procedures for the selection of flight crews for the army air forces. This section was headed by the psychologists, M. Richardson and D. E. Baier, during the first period of the war. It concentrated its efforts primarily on problems of initial classification and of selection for specialist training. Its task demanded constant revision of the testing program, both because old psychological instruments had to be adapted to the practical requirements of military situations and because the needs of the army changed from time to time. In addition to tests, the section prepared standardized aids for field work for the classification officers, manuals of test administration, interview schedules and rating forms.

The initial step in the classification of the army recruit

was the administration of a minimum literacy test to detect the men who would not be able to absorb military training without special instruction. Illiterates were then given a visual classification test to eliminate those without sufficient native ability to learn military duties. For literate men the next step was the army general classification test, a test of general learning ability which replaced the army alpha of World War I fame. It was given to every literate inductee after Oct. 1940. It was revised three times before the end of the war on the basis of research findings, but all forms were roughly comparable and contained three types of items: vocabulary, arithmetic and block-counting. Men were classified into five groups according to the learning ability shown in the A.G.C. test, and many with superior scores were assigned to various specialist training courses. The correlations between showing on the A.G.C. test and grades in training courses ranged from .20 in teletype maintenance to .73 in aircraft warning. In addition, recruits took a mechanical aptitude test and the radiotelegraph operator aptitude test (later replaced by the army radio code aptitude test). For radiotelegraphy, experiment showed auditory discrimination to be less significant than a work sample test of code learning.

The value of the testing program for assignment according to aptitude was impaired by the necessity of adjusting to the constantly shifting quota demands of the various branches of the service. Men well-qualified for specialized tasks might have these qualifications ignored because the immediate quota-need was for routine army duty. And once assigned to a unit, reassignment was difficult because few commanding officers liked to release good men. Part of the failure to utilize superior ability and special skills more completely was unavoidable, but it was also true that better planning and less rigidity in reassignment were possible.

Men who showed poor learning ability on the test were placed in special training units under experts who had developed considerable original instructional material designed to increase motivation by its freedom from rigid and static content. In this way psychological training salvaged many recruits who otherwise would have been dismissed as mentally unqualified.

The need for highly trained technicians and for officers led to the army specialized training program in Dec. 1942. This program utilized the resources of the country's educational institutions and assigned soldiers to those colleges where the army had set up a curriculum. The A.S.T.P. included a basic phase and an advanced phase, the latter divided into various specialized curricula. Criteria for admission to A.S.T.P. included high scores on the A.G.C. test and an educational achievement test also prepared by the personnel research section. In addition, the section constructed standard objective tests to evaluate progress in A.S.T.P. courses. The 150-odd tests developed, constituted the largest single objective-testing program in the college field.

To increase the number of trained personnel psychologists in the army, one of the advanced A.S.T.P. curricula was devoted to personnel psychology. This curriculum, offered during 1943 at 11 leading U.S. universities and staffed mainly by psychologists, had an assignment of 1,350 candidates, a number of whom were later commissioned.

Clinical psychologists were assigned to a variety of tasks in the army. Their main use was in medical installations and hospitals. During 1944 the Office of Chief Clinical Psychologist was established to co-ordinate and supervise

clinical work in the army, and Lt. Col. M. Seidenfeld was named to this office. The program included clinical psychological services in all general hospitals of 1,000 or more beds. These services covered: counselling of convalescent patients who were expected to return to military duties, preparation and interpretation of clinical records and test results for the officer in charge, aiding in psychological problems related to retraining psychoneurotic casualties, and assisting in the determination of assignments consistent with the convalescent's physical and mental state. Clinical psychologists also served in developmental battalions where the task was one of reconditioning men whose morale had broken badly.

Another use of the clinical psychologist was in the rehabilitation centres of the individual service commands, where attempts were made to salvage certain offenders under court-martial conviction. At the disciplinary training centre in the Mediterranean theatre of operations, for example, a psychological clinic was established in which all prisoners were systematically tested and interviewed. Aptitude and intelligence examinations were supplemented by personality tests. A malingering key was developed in the testing procedure to detect simulated defects from bona fide failures on the principle that the malingerer would follow a different pattern of error from that of the genuinely subnormal person. The clinic made the following types of recommendations: restoration to military duty for trainees with no specific personality defects who were making satisfactory progress in disciplinary training; reclassification to limited duty for those showing psychoneurotic tendency; return to the zone of the interior for further rehabilitation for those with major defects of personality, either mental or emotional, and hospitalization for severe cases of neuroses and psychoses.

The clinical program of the army expanded in the closing years of the war to provide psychological and vocational counselling for veterans at separation centres. The pressure of discharging millions of men in a short period and the soldiers' eagerness for a speedy separation process meant that the major part of the job was left for the Veterans' administration.

The research unit of the morale division had the function of evaluating informational programs in the army and studying the enlisted man's reactions to army problems. The experimental section of this unit under the psychologist, C. Hovland, pretested films and educational programs on small groups before they were widely circulated through the army. A surveys section conducted attitudinal research on specific problems of morale using both oral interviews and written questionnaires. In this operational research a new instrument was developed in the Guttman scaling device, which simplified the determination of the true scales or dimensions of attitude by statistical grouping of answers to related questions.

U.S. Army Air Forces.—The A.A.F. utilized psychology in its selection and research program more thoroughly than any other branch of the U.S. services. The skills involved in piloting various types of planes, in navigation, in bombing, in aerial gunnery, required careful analysis and much experimentation for the construction of diagnostic tests. About 200 commissioned officers were assigned as aviation psychologists to the A.A.F. psychology program with approximately 750 enlisted men, many of whom had B.A. or M.A. degrees in the field of psychology or education. Col. J. Flanagan headed the psychological branch in the Office of the Air Surgeon.

Applicants for aviation cadet training had first to pass the aviation cadet qualifying examination which was vali-

dated against success in actual flying training. The examination included verbal, interest, perceptual, judgment, mechanical comprehension and mathematics tests, the most useful of which proved to be the mechanical comprehension and interest measures. Successful applicants were given basic training after this examination but still had to pass cadet classification tests which helped to determine the assignment to the separate training programs for pilots, bombardiers and navigators or to their rejection and assignment to enlisted aircrew or ground crew training. Research established these findings: (a) tests with heavy verbal-intellectual or mathematical loadings had considerable validity for the prediction of navigator success but were poor for pilot selection, (b) certain mechanical and information tests were useful predictors of pilot success, (c) other predictors of flying ability were psychomotor measures and a control-confusion test, sampling the individual's ability at delicate but rapid manipulations of controls in a complicated sequence under conditions productive of divided attention, (d) in general, aircrew success was related to previous active participation in sports.

As the war progressed, validation of the tests against combat performance became an important project. Emphasis shifted, too, from selection tests to instructional procedures to establish reliable and valid measures of progress and proficiency in training. Finally, attention was given to the design of the plane and its apparatus for maximum psychological efficiency in operation.

The significance of the contribution of psychologists to the A.A.F. was summed up in the second report of the commanding general of the army air forces to the secretary of war, Feb. 27, 1945, which read in part as follows:

The battery of 20 psychological tests used for classifying all candidates for pilot, navigator, bombardier, and aerial gunnery training has proved valid in predicting not only an aviation cadet's chance for winning his wings but also the flier's chance for combat success. In a follow-up study of both bomber and fighter pilots in the European theatre, it was determined that pilots who had scored highest in the psychological tests administered before they learned to fly tended to be rated by the squadron commanders as most successful in combat. Likewise, those who had the minimum acceptable scores appeared to be the most frequently missing in action.

The Aviation Psychology Program in the past year has been extended to a point where it contributes to the number of bombs which hit within the target areas . . . [It] has paid off in time, lives and money saved, and through its selection of the raw material has aided in the establishment of an effective combat air force. This has been done at a total cost of less than \$5.00 per candidate tested.

In contrast to the continuing development of U.S. aviation psychology, the Germans, as has been noted, gave up applied psychology in the middle of the war. The Japanese, however, copied old testing procedures in the selection of air cadets but their program was exceedingly limited as compared to U.S. efforts, and there was no attempt at discriminative aptitude scores for the specialized air jobs. It is of interest that the "kamikaze" pilots were not selected but were volunteers. The Japanese army, however, offered unusual rewards: the pilot could go on leave immediately (a very rare privilege in the Japanese army), he was given any special foods he wished, he was encouraged to indulge himself sexually, and was allowed within limits to choose the time of his death by naming the time of his mission. Contrary to popular opinion, the morale of the kamikaze pilots was bad. After the enjoyment of their special privileges there were many excuses and attempts to get out of the final death mission.

U.S. Navy.—To select the best qualified men for the various types of naval training and to evaluate the training itself was a large-scale research operation involving con-

stant test revision as the measures proved valid in varying degrees against actual success in training and on the job. This operation was the responsibility of the test and research section of the bureau of naval personnel. The section developed a basic test battery which was administered to about 2,000,000 men. In addition, it constructed achievement examinations for the navy schools, and tests for the selection and classification of officers.

Clinical psychologists in the navy, numbering about 100, worked under the neuropsychiatric section of the bureau of medicine and surgery. They were assigned to training-station selection units, naval hospitals, precommissioning ships, receiving ships, embarkation centres, disciplinary activities and retraining programs. Psychologists functioned both as independent examiners and as consultants to the psychiatrists but under their direction.

The bureau of medicine and surgery commissioned another 100 psychologists for the naval aviation program. These aviation psychologists performed a variety of functions. In the field service organization they administered tests, did general and psychological counselling with cadets, and helped to standardize flight instruction. In the procurement and personnel organization they also functioned in an all-around capacity as well as test administrators. They contributed at many boards to making the selection-interview a reliable and valid means of evaluation. In the central research group they revised and validated aviation tests.

The navy also gave considerable attention to the problem of the psychological design of equipment and apparatus. At the end of the war a whole section was set up in the naval research laboratories for continuing experimentation on apparatus-design to make for ready learning and optimum efficient use by human beings.

War Agencies.—The selection of agents for the highly difficult and hazardous intelligence work of the Office of Strategic Services (*see* WAR AND DEFENSE AGENCIES) was a major undertaking. Leading psychologists and psychiatrists were called in to aid in the selection and training of personnel. The testing situations devised marked a radical departure from traditional psychometrics. The total person was studied in life situations. Candidates, for example, upon reporting to assessment camps had to live there for several days under assumed identities, with complete loss of former social status, and with no knowledge of the extent to which problem-situations were staged. In addition to the assessment of candidates OSS utilized psychologists in the analysis of intelligence materials.

In the Office of War Information (*see* WAR AND DEFENSE AGENCIES), the main function of psychologists was the systematic evaluation of the effectiveness of the organizations informational programs and an analysis of any intelligence materials of value in the planning of these programs.

Both the surveys division of OWI and the program surveys division of the department of agriculture undertook social surveys for other government agencies to aid them in their administrative problems by this type of grass-roots research. For example, studies were made of industrial morale in the shipyards and in other war industries for the war department and for the War Production Board. Results showed that morale and production could be kept at a high pitch in spite of congested living conditions in a mushrooming war community, if the in-plant conditions of work were favourable.

Related to this type of attitudinal research was the work

of psychologists in the Office of Civilian Requirements of the War Production Board. The problem here was the programming of production of just enough essential civilian goods to keep the domestic economy functioning. O.C.R. conducted its own surveys under the direction of psychologists to obtain estimates of the available goods in consumer's homes and of consumer needs.

In the fall of 1944 an authoritative civilian survey was set up in the office of the secretary of war to make an objective evaluation of the effects of strategic bombing upon Germany. The purpose was threefold; to assess the importance of strategic bombing as against other weapons, to advise the joint target group in the air war against Japan, and to see what lessons could be learned about defenses against bombing. Social psychologists were recruited for the morale division of the survey to determine how the capacity and the will of the German people to resist was affected by bombing. Preliminary studies were made in the spring of 1945 of captured German mail, of German prisoners of war, French escapees and civilians in captured German towns. For purposes of the final study, conducted in June and July 1945, Germany was divided into city groups on the basis of bomb damage, from unbombed to heavily bombed cities. Cross sections of the populations were interviewed in these areas, official German intelligence reports on morale were consulted, and displaced Russians, Poles and Italians were questioned. Since the extent of bombing was already established, the interview schedule with German civilians did not ask directly about the effects of bombing but asked about many aspects of morale. The relative level of morale in areas undergoing different amounts of bombing could then be ascertained without being affected by respondent co-operation. The results showed little confirmation of the belief that bombing strengthened morale. The German will to win was seriously depressed by the heavy air attacks, and the majority of German civilians were ready to surrender long before the end.

They remained in the war because of repressive nazi controls and because of lack of revolutionary initiative among the German people. The findings indicated, however, that continued heavy bombing did not bring successive decrements of morale. After a few raids, people became wholly concerned with problems of fox-hole existence and grew politically apathetic. German industrial morale also declined under bombing but production was maintained for a long time by nazi penalties, rewards and countermeasures.

By the fall of 1944, however, bad cracks appeared in the structure and in a few months the collapse was complete. (See also MEDICINE; PSYCHIATRY; PSYCHOLOGICAL WARFARE; SOCIOLOGY.)

Public Health Engineering

Water Supply.—The problems of water supply during the decade 1937–46 were dominated to a considerable extent by the preparations for and the experiences during war. Developments for the most part centred around emergency conditions. Special field equipment and practices arose in order to prevent or to correct the disorganizations under war conditions. Unusual amounts of water were provided in most war-torn countries for fire-fighting purposes, and severe interruption or complete elimination of services resulted from the destruction of dams, pumping stations and distributing lines.

Complete destruction of one of the largest rapid sand water filtration plants in Europe occurred in Warsaw, Poland, paralleled by the destruction of the great Tirso Power dam in Sardinia, Italy, and by the subsequent destruction of power and water dams in Germany. Events such as these led, however, to the development of extensive emergency programs and of standardized units, capable of rapid application to emergency conditions. These ingenious programs, covering everything from provisions of power facilities, treatment devices and distribution facilities marked one of the high spots in war emergency undertakings.

Civilian defense authorities in the United States provided for similar possible emergency conditions. Much time, energy and money were expended in extra precautions for the operation of key sources of supply. In some instances duplication of plant and equipment was provided, and important advances were made in interconnection between the water systems of adjacent municipalities.

One of the important general projects throughout the world was the provision of increased sources of water, primarily to meet the unprecedented demands of war industries. Although these demands were concomitant with decreased availabilities of construction materials, the situations were met, and even in devastated areas water supply interruption was remarkably limited. The experience of Coventry, England was illustrative of this fact.

In the U.S., developments of sources of water supply progressively farther from distribution centres became essential to meet the increased demands. Large and extensive works were undertaken and partly completed in such major urban areas as New York City, Los Angeles, Boston and Denver. The largest filtration plant in the world was completed in Chicago, Illinois.

Expediency controlled adherence to lower standards of hygienic quality of water in many countries. In spite of these concessions to disaster, however, remarkably few water-borne epidemics occurred throughout the world. Many thousands of cases of enteric disturbance of water-borne origin did occur, however, through the collapse of supervisory functions and the introduction of unusual hazards in cross connections between potable and non-potable water supplies. Large as these numbers were, they were intermittent in occurrence, widely distributed geographically and remarkably few considering the unusual conditions of stress under which most waterworks systems operated.

The London Metropolitan Water board, for example, reported shortly before the end of World War II that there had not been a single case of water-borne infection

following air raids in their jurisdiction—a truly remarkable demonstration of administrative efficiency and responsibility.

Relatively little destruction of plants and structures occurred through sabotage. Contamination of water supplies by aerial attack was virtually unknown. Neither chemical nor bacterial contamination of water supplies was practised, even though precautions for meeting such contingencies were developed in almost every country.

Although there was some evidence that contaminated drinking water might be a means of communicating poliomyelitis, most authoritative epidemiological data did not verify this hypothetical possibility. It was demonstrated, however, that the gastrointestinal tract is a possible source of poliomyelitis from the human body. The active virus of this disease was recovered from the stools of patients and from city sewage.

Furthermore it was disconcerting to find that the virus lives in sewage for a considerable time and in pure water for at least 100 days, and that ordinary processes of water purification do not destroy the virus completely. A great deal more work remained to be done, however, before it could be said that water was an important vector for poliomyelitis. (See also INFANTILE PARALYSIS.)

The relationship of fluorine in water supplies to protective action against dental caries in certain young age groups was given a great deal of attention during the decade. It was reasonably demonstrated that an inverse relationship exists between the prevalence of dental caries and the fluorine concentration of municipal water supplies. A sufficient amount of study was devoted to this problem to lead to the reinforcement of domestic water supplies with sodium fluoride so as to bring the fluorine concentration to a figure exceeding 1.0 p.p.m. (parts per million). It was generally accepted by most investigators that water supplies with fluorine concentrations of less than 0.5 p.p.m. create serious disabilities.

Full plant scale applications of sodium fluoride to the public water supply were carried out with parallel control undertakings in Kingston and Newburgh in New York state; Brantford, Ontario, Canada; Grand Rapids and Muskegon, Michigan and in several cities in Texas. Simultaneously, many thousands of school children were examined annually to determine the variations in their dental condition during their school period and in relation to the fluorine concentrations of the water supplies. (See also DENTISTRY.)

World War II naturally intensified the necessity for developing important techniques and equipments for water treatment in both stationary and mobile field undertakings. Both the army and the navy used diatomite water filters on a limited scale, since they were effective in the removal of causative organisms of amoebic dysentery and of schistosomiasis. Toward the end of the war, new chemical derivatives were developed for field use as superior substitutes for the generally used chlorine compounds. Many of these were iodine organic compounds in which the iodine was loosely held and readily available for bactericidal and cysticidal activities.

Epidemics of infectious hepatitis which occurred in various parts of the world appeared to have their origin in sewage-polluted waters. In many instances they were attributed to gross sewage pollution of unprotected surface and underground waters. Heavy chlorination of water seemed to provide adequate protection against the virus of this disease.

Heavily polluted underground waters were under additional suspicion as causing the death of infants. This

was one of the few examples of the possible detrimental effect of high chemical concentration of nitrate compounds in heavily polluted farmyard wells. Such high nitrate-containing waters, when ingested by infants, resulted in the production of nitrites through the bacterial action. The nitrite ion was absorbed and oxidized the haemoglobin of these children to methaemoglobin with resulting cyanosis, and death.

Synthetic ion-exchange resins reached such a high state of development and use that they were applied to large scale central demineralization units for water supply, particularly in industrial plants. These new procedures resulted in the availability of a purer water at a lower cost than was formerly produced through distillation.

Cathodic protection of metal structures for corrosion control provided an additional medium for meeting this great plague of water-supply structures. The application of sodium hexametaphosphate in dosages as low as 2 p.p.m. added to the available measures in this same field of anti-corrosion activity.

Sewage Treatment.—No startling developments were reportable in this field during the decade. Biological processes were still being less favoured than those with a chemical and mechanical means of treating sewage. The handling of sewage sludge passed into the field of vacuum filtration followed by either incineration or drying. The Chicago Sanitary district exemplified one of the largest installations of the combination of vacuum filtration and drying.

In spite of the general trend toward mechanical operations in the U.S., the more complete bio-oxidation processes appeared to be favoured in Great Britain and on the continent, with the completion of the great works of the West Middlesex Main Drainage program at Mogden, serving more than 1,000,000 people.

Increasing use of sludge gas for power was evident in some 150 installations of gas driven engines in the U.S. alone during the decade.

Air Sanitation.—Complete agreement was not reached during the decade on this very significant problem of public health engineering. A great deal of information, experimental and practical, of course, had been acquired on the manner of formation of droplet nuclei; the rate of settling of such materials; the longevity and virulence of air-borne pathogenic organisms; and the destruction or removal of such organisms by ventilation, air filters, aerosols, ultraviolet light, treatment of bed clothes and of floors.

In spite of these extensive studies, however, general agreement on the significance of air-borne infection control was not reached. The public health significance of this mode of transmission of contagious diseases, especially those of the respiratory tract, was still being debated, and activity still proceeded on many fronts in further refined studies of each of the aspects enumerated above. Military and civilian experiments of elaborate character were actually used in connection with activities on the war and home fronts.

Improvements were made in the use of aerosol, vapour or mist disinfectants sprayed into the room. Ultraviolet light was used in large scale experimental studies. They all disclosed that many of the available materials and devices are capable of reducing materially the bacteria in the air. Much of the bacteria density in the air, however, apparently resulted from blankets, bed linens and the floors of sleeping and living quarters. These findings in

turn led to intensive studies on the use of various impregnating oils to be incorporated into bed clothes, in the laundering processes and to be applied on the floors for the settling of dust.

Two major questions in this new field of environmental sanitation still remained unanswered. They were: (a) where and under what conditions is droplet infection sufficiently important to warrant control; and (b) what methods are most effective and economical.

To say that both of these questions still remained unanswered is not to discount the fact that a new field of environmental sanitation of major importance to human health and welfare was opened during the 10-year period.

Refuse Disposal.—Two trends-marked developments in the field of disposal of garbage and rubbish. High temperature-destruction of these materials was the first; in the U.S. the construction of new incinerators for this purpose made great strides. The second development was in supervised land-fill as an economical and sanitary method of disposal of refuse. Operations in New York city, San Francisco, Detroit, Baltimore, and in many undertakings of Great Britain, all demonstrated that land-fill procedures, conscientiously supervised and administered, were cheap, sanitary and effective.

The grinding of garbage, both on the household and on the community basis, was also introduced into common practice. St. Louis, Mo., for example, disposed of an average of 400 to 500 tons of refuse daily by fine grinding and discharge into the Mississippi river.

Disposal of garbage jointly with sewage was practised in Gary, Ind.; Lansing, Mich.; Rock Island, Ill.; Findlay, O.; Goshen, N.Y., and Marion, Ind. Although such methods produced an increased loading on the sewage treatment processes, this fact was not found to be a major deterrent, if adequate provision was made for such increased loads.

The household garbage grinder represented one of the major advances in the handling of garbage on private premises. It eliminated the objectionable collection can and the equally objectionable collection by trucks.

Insect Control.—The diseases caused by mosquitoes, flies, cockroaches, fleas, lice, mites and other insects represent the largest category of hazards to health in the world. The great scourges of malaria, typhus, bubonic plague and dengue fever again demonstrated their public health importance with renewed vigour during the 10 years. Fortunately, the same period witnessed outstanding contributions to the control of disease in the development and use of DDT or dichloro-diphenyl-trichloroethane; of insect repellents; and of the "building out" of mosquito-breeding areas of large size. The latter procedure was eminently successful in the work performed on the impounding reservoirs of the Tennessee River valley, perhaps the largest demonstration in the world of this successful type of permanent elimination of mosquito-breeding areas. Although the discovery of DDT was not properly to be allocated to the period 1937-46, since it was first synthesized during the 19th century in Germany, its rediscovery and its application in 1940 to the potato crop in Switzerland revived and extended universal interest in it.

Although much work still remained to be done with respect to the comprehensive applications of DDT, there was little reason to doubt that the fields of application for public health purposes as well as for improving the agricultural economy had by no means been exhausted. It lent itself to application by aeroplane dispersion and by spraying on the walls of houses, thus extending its successful use with constantly diminishing costs. The prospect for reducing materially and economically the insect-borne diseases throughout the world was promising. (See also ENTOMOLOGY.)

Rodenticides.—Rodents, as reservoirs of diseases affecting

Purification plant built at Reelfoot lake, Tenn., with equipment specially designed for treating suburban water supplies

man and as predatory animals, had resisted control for centuries. In this activity, again, war-created shortages of chemicals formerly used as rodenticides, actually pressed forward the search for substitutes or better chemical compounds for these purposes. Two effective materials developed during the decade gave promise of superseding the more familiar conventional ones of the past. Sodium fluoracetate or "1080," and alpha-naphthyl thiourea or ANTU, were promising compounds of this period. Both were highly toxic, stable, dependable and acceptable to rats and perhaps to many other rodents.

Housing.—Throughout the world, the 10-year period saw a more complete deterioration in housing facilities than perhaps any previous period within a century. Aside from the fact that destruction of houses by deliberate intent exceeded any known in history, the period was paralleled by almost complete absence of the construction of new and permanent houses. The 10-year interval, therefore, measured a declining availability of facilities for living. Energy was directed primarily at continuing the studies on the hygiene of housing, pre-eminently through the Committee on the Hygiene of Housing of the American Public Health Association. Data were made available on the technique of evaluating housing facilities with particular reference to living space, sanitary facilities, light and air. Detailed guides were thus prepared for the determination of the quality of existing or proposed housing, so that investigators might have objective criteria by which to plan and to evaluate their programs.

No major progress could be reported in urban redevelopment programs, although permissive legislation for such redevelopment was enacted in a number of the cities of the United States. The only major demonstration, however, of the application of such legislative measures was in the Metropolitan Life Insurance project in New York city. Its significance in reducing blighted areas through private investment remained to be demonstrated and evaluated. In continental Europe and in the eastern countries many factors of war prevented anything more than thoughtful planning for the future. (See also EPIDEMICS AND PUBLIC HEALTH CONTROL; HOUSING; TOWN AND REGIONAL PLANNING.)

Public Opinion Surveys

The history of public opinion surveys of the representative sample type coincided closely with the decade 1937–46. The *Fortune* Survey of Public Opinion and the American Institute of Public Opinion releases had first been published in 1935. The British Institute of Public Opinion began publication in 1936, followed soon by Mass Observation. Similar "polls," as they were popularly named, were established in Canada in 1941, in Australia in 1941, in Sweden in 1942. After the end of World War II in 1945, polls were established in France, Italy, Norway and several other countries. By late 1946, most of the world's population outside of Asia, Africa and Eastern Europe was represented by some sort of poll, public or private, regular or intermittent. Because of these polls it became possible to measure the history of the decade in many countries of the world in a manner in which no previous decade of human history had ever been measured before.

A complete measurement by these means, however, remained a possibility only. Most of the published polls were undertaken for journalistic purposes, and many of these for the purpose of estimating the election strength of various political candidates. Thus, although an estimated total of some 50,000 questions were asked by the major polling agencies in the U.S. alone and many thousands more in other countries, the interest of the agencies was mainly in current news. Social scientists and historians made no comprehensive synthesis of the mass of data accumulated. Reliance must therefore be put on the occasional and partial recapitulations made by the polling agencies themselves. From these summaries certain conclusions were drawn concerning the trends of public opinion and the ways in which public opinion is formed. The more significant of the findings so established are outlined in the following paragraphs.

The "New Deal."—The start of polling revealed that the people of the U.S. by a majority of about two-thirds were in favour of having the federal government take the ultimate responsibility for seeing to it that all who were willing and able to work had jobs. This opinion reversed what was believed to be the traditional U.S. attitude toward government participation in economic affairs and constituted an endorsement of the economic responsibility which the Roosevelt administration had assumed. Majorities of the public continued to favour most of the principal administration measures with the exception of the effort to revise the terms on which the justices of the supreme court held their offices.

Public approval of the New Deal program, including its labour legislation, carried through the war period and into the postwar reconversion, and was sustained in the face of strikes and other economic disturbances. As early as 1938, however, it became apparent that the public was tiring of those who had initiated and administered the program. The polls indicated, as clearly as it was possible to indicate a historical hypothesis, that Roosevelt would not have been elected to a third term if the war emergency had not arisen. After the war and Roosevelt's death, the delayed reaction in favour of the Republican party took place. But there was no indication that the people in changing leadership were abandoning support of the New Deal program.

British Resistance.—Mass observation, using standard polling methods and several variants thereof, investigated the British public's reaction to many wartime meas-

ures. One variant, a sample count of civilians carrying gas-masks as requested by the government, revealed the progressive steadying of British nerves as the war went on. When war was declared in Sept. 1939, a high percentage of civilians carried gasmasks. The percentage dropped off sharply during the winter, to rise again with the fall of France. At the start of the battle of Britain it rose once more, but not so high as it had previously. It soon dropped to a negligible percentage and remained there even when the German attack on the U.S.S.R. was announced.

U.S. "Road to War."—When Germany attacked Poland in 1939, U.S. newspaper editorials for a period of several weeks seemed to be written on the assumption that the U.S. would soon be at war with Germany. A majority of the public did not take this view. While accepting the possibility of war, they hoped to avoid it for as long as possible. They sidled toward war in a series of steps, all short of war. Public opinion first approved revision of the Neutrality act to a "cash and carry" basis. When it became clear that British cash would not be sufficient for war purchases, the public approved lend-lease. When it became likely that deliveries could not be made without the help of the U.S. navy, the public approved convoying. Asked first whether convoying should be undertaken to get goods to Britain, a majority said "yes." Asked then if a U.S. naval vessel were to be sunk in convoy work, should the U.S. go to war, a majority said "no."

During the same period, the U.S. public gave up its feeling of geographical isolation. Before the war a majority of the public was unwilling to defend even Central America against foreign attack. Only a bare majority was willing to defend Hawaii. After war began in Europe, a majority became willing to defend South America down to the "hump" of Brazil. As war progressed, the ramparts were stretched farther and farther out both on the Atlantic and the Pacific sides. Just before Pearl Harbor was attacked, a majority was willing to defend Australia and the Netherlands Indies to the west, Britain and West Africa to the east. The sense of belonging to the world, thus established, persisted during the period of U.S. participation in the war and during the period immediately following. All polls showed the U.S. public in favour of taking active part in some sort of world organization.

Event vs. Argument.—One of the chief findings of the polls concerning opinion formation was their demonstration of the relative ineffectualness of argument and persuasion. It was long suspected that newspaper editorials did not win elections, but careful polling showed that the whole apparatus of the political campaign achieved hardly anything in swaying votes; it merely helped to get the votes out by arousing interest. Public opinion, in fact, was shown to be not fickle, but remarkably stable. This stability was somewhat obscured by the journalistic pressure on the polls to follow the news. Therefore, most polling continued to be done in those areas where opinion was in the process of formation or was being changed by events. Events measurably change public opinion. Each step in the "road to war" described above was taken in response to events. But where events were minor or did not appreciably affect the situation concerning which an opinion had been formed, then public opinion scarcely moved from year to year, no matter what arguments were presented.

Opinion and Information.—Another basic finding of the polls concerned the relation of opinion to information. People who are well educated and well-to-do economically

are usually well informed also. Of these three correlated criteria, information seems to have most to do with the character and range of opinions held. In general, those who are well informed on current affairs hold definite opinions on a greater number of topics than do those who are poorly informed. The well informed also tend to hold moderate opinions on the topics they have considered, whereas the poorly informed tend to hold more extreme opinions. If democratic government depends for its effectiveness on a wide spread of moderate opinions, and if few and violent opinions are prejudicial to it, then the democratic faith in education, information and economic competence had been demonstrated to be sound by scientific polling methods. (See also PSYCHOLOGY.)

Public Relations

The growing complexity of society made all groups increasingly aware of their dependence on public approval. The great changes which took place after World War I in the social, political, economic, technological and psychological aspects of society led to intensified insecurity, group alignments and disparities. Such developments made it essential to establish methods whereby groups might adjust to change and become integrated with life's changing patterns.

Public relations became a recognized profession and tool of integration between 1937 and 1946. In 1937, the depression psychology of business and other social forces was giving way to confidence. Shortly thereafter, the impending war changed public psychology. In 1940, the United States became a public relations battleground for conflicting ideologies, with broad issues displacing sectional problems as the public's main interest. Public relations turned to strengthening democracy.

From 1941-45, U.S. public relations efforts were devoted almost exclusively to the war program. With hostilities' end in 1945, it was obvious that the U.S. was to go through a period of difficult adjustments. A contest took place among all groups to improve their positions with the public.

In 1937, the government made little distinction between publicity, public information and public relations. From 1941 to 1945, the government organized large public relations departments. The Office of War Information, a giant public relations service, had a peak wartime personnel of 5,693.

The public relations efforts of the U.S. army and navy stressed the building of morale among civilians, workers and the armed services, strengthening good-will with the United States' allies, winning over the neutrals and defeating the axis.

The year 1946 found public relations entrenched as a function in government. Research of public attitudes, distribution of readable information and co-operation with media, became standard practice. The U.S. budget bureau in 1946 reported that government publicity costs amounted to \$75,000,000 during the fiscal year. Employees on full-time numbered 23,000; 22,769 were engaged part of the year.

Diversity of Users.—Public relations achieved new and enlarged status in industry. Public relations experts became high officers of corporations. Some headed trade and professional organizations. Businesses added and expanded their public relations departments with responsible directors at the head. Advertising agencies expanded their

public relations departments. The National Association of Manufacturers, the U.S. Chamber of Commerce, the American Association of Advertising Agencies, the Association of National Advertisers and many other trade associations and individual organizations undertook public relations activities. Labour expanded its public relations effort to build good-will with the public.

The great media—press and radio—became aware of public relations as a tool of management and discussed the subject with growing understanding. Advertising was used to sell business as an institution to the public. State publishers' associations and individual newspapers engaged in public relations activities. As an example, the National Association of Broadcasters adopted a code of fair practice in 1939-40.

Organized social service adopted public relations procedures, as did minority groups—racial, religious and political—to advance their causes.

Education emphasized the importance of public relations. The National Education association adopted a broad public relations program carrying on activity to improve the whole educational field with the public.

The first course on public relations was given at New York university in 1923. In 1937, 68 such courses were given at U.S. universities. The 1946 bulletin of New York's New School for Social Research, listing 11 courses, was typical of the academic approach. The first workshop in public relations was held in Oct. 1945, at the California Labor school in San Francisco. Universities extended frequent lecture invitations to public relations practitioners. Study of this field was an adjunct to courses on political economy, sociology and social psychology. Many universities had employed directors and departments of public relations.

Artists made similar determined public relations efforts to stimulate public understanding and interest in art.

Rise of Publicists.—The number of independent public relations counsel multiplied during this decade. In 1937 the New York classified telephone directory listed only 36 public relations counsel; in 1946 there were 219. In Chicago the increase in the same period was from 9 to 68. Los Angeles in 1946 listed 30; Washington, D.C., 25. The magazine *Advertising Age* estimated that, in 1946, the 20 top publicists in New York and Chicago shared total fees in excess of \$3,000,000 yearly.

The first *Public Relations Directory and Yearbook*, issued in 1945, listed 455 independent practitioners in 65 cities and 24 states; 3,870 business firms employing public relations directors; 1,216 trade and professional groups, and 588 social service, religious and other nonprofit organizations doing public relations work.

During this period, public relations groups were organized on geographical, trade and professional lines. The American College Public Relations association membership grew from 302 in 1937 to 518 in 1946; National Publicity Council for Health and Welfare Services increased from 1,200 to 2,000; the Library Public Relations council, from 6 in Jan. 1939 to 210 in 1946. Among other groups were the Publicity Club of New York, Publicity Club of Chicago, Fifty Club of Philadelphia, and Public Relations Group of Los Angeles. The National Association of Public Relations Counsel, Inc., organized in 1936, 10 years later had 345 members in 30 cities and 14 states; the American Council on Public Relations, American Public Relations association, American Trade Association Executives and other groups had entered the field.

Publications.—Special periodicals were established to deal with public relations. *The Public Opinion Quarterly*,

published by Princeton university, was established in 1934; *Channels*, published by the National Publicity Council for Health and Welfare Services, in 1938; and *Publicity Problems and Publicity Digest* by the American College Publicity association, in 1942. *Public Relations News*, a four-page leaflet, was issued weekly.

The American Journal of Sociology, *The Journal of Social Psychology*, *The Journal of Social Issues*, and other periodicals continued to discuss public relations. *Tide*, *Printers' Ink*, *Sales Management*, *Advertising and Selling*, and *Advertising Age*, trade papers in the sales and advertising field, devoted substantial space to the subject.

Learned and professional societies' publications recognized public relations. *Propaganda and Pressure Groups* was published by the American Academy of Political and Social Science in 1935.

The Society for the Psychological Study of Social Issues, American Marketing society, American Sociological society, American Association for Adult Education, American Political Science association and Social Science Research council covered aspects of public relations in their researches and reports.

Public Utilities

The decade ending with 1946 was as eventful a period as any in the history of U.S. public utilities. The first half was dominated by the New Deal legislation as that congeries of measures sought to overcome the accumulating difficulties of public utility control made manifest during the depression beginning in 1929. The last half brought the overshadowing importance of another world war, in consequence of which public utility plants were put through the strains of serving the needs of a war economy with the objectives of the New Deal reforms only partially achieved.

Developments in Regulation.—After World War I, economic and technical conditions were favourable for a rapid expansion in the public utility plant of the United States and in the extension of service. In the course of the 1920s, this involved much corporate reorganization, with the business becoming more and more interstate in character. Even before the depression, state regulatory commissions felt that they were without sufficient powers to deal with the widespread and interwoven corporate structure of the electric, gas and communications industries. Under the leadership of New York and Wisconsin, a number of states, after investigation of conditions, made extensive commission reorganizations in an effort to meet the changes which had occurred in these regulated industries. The adequacy of this reoriented state regulation to protect consumer interests without aid from federal agencies was, to say the least, debatable.

The depression focused public interest upon the expanded character of the utility industries and especially upon the abuses associated with holding companies and their security issues. This coincided also with a revival of the movement for the conservation of natural resources. Thus there was widespread political support for a national administration committed to a program of reform and expansion in federal regulation.

The steps taken may be briefly reviewed as follows: (1) Radio broadcasting companies, formerly under the Federal Radio commission of 1926, and interstate telephone and telegraph companies, under the Interstate Commerce commission since 1910, were in 1934 placed under a new Federal Communications commission. (2) Regulation of interstate motor carriers was added to the duties of the Interstate Commerce commission. (3) A Federal Power commission had been set up by the Federal Water Power act of 1920 as a part-time, ex-officio body to administer a system of licensing of water powers on interstate streams and on the public domain. Amendments to this act in 1930 reorganized the commission into a full-time agency. The significant change came with the enactment of title II of the Public Utility act of 1935, which vested in the commission regulation of rates and service of electric utilities in interstate commerce, supervision over mergers, sales or transfers of property, over security issues and over other matters. Where the commission's powers under the act overlapped with those of the state commissions, the latter were accorded a priority of jurisdiction, but the federal agency was instructed to co-operate with the state commissions. In 1938 it was accorded a similar jurisdiction over artificial and natural gas utilities. (4) The Securities and Exchange commission administered three statutes: the Securities act of 1933, a "blue sky" law first administered by the Federal Trade commission; the Securities Exchange act of 1934, which created the commission; and title I of the Public Utilities act of 1935. This act declared that "public utility holding companies and their subsidiary companies are affected with a national public interest" and provided measures designed to give control over their activities, notably security issues and contracts with service companies, the abuses of which had handicapped the regulation of operating utilities because they were outside the reach of state commissions.

The Holding Company Problem.—The public utility holding company problem began with the mushroom growth of these agencies in the 1920s. Once New Jersey had opened the way for its legal existence, the holding company began the process of integration, in the course of which valuable services were rendered to subsidiaries in financing, in the supervision of construction, in the purchase of materials and generally in supplying engineering, managerial and legal counsel. Of the 57 utility holding companies doing business in 1935, fully 41 were chartered between 1922 and 1932.

A prolonged investigation by the Federal Trade commission yielded abundant evidence of the abuses which had crept in along with the sound achievements. In face of the impotence of the state governments to deal with them, and owing to the lack of "arms-length bargaining" between parent and subsidiary, the charges for service performed were generally adjudged excessive, since the test of a freely competitive market was absent. The pyramided holding company exercised an effective if tenuous control over a wide range of operating utilities, building up financial empires which challenged the regulating powers of

government. In the end it was a struggle between the economic power of syndicated capital and the political power of government operating under a federal system. The combination of the principle of trading on the equity (inherent in any corporation which borrows a portion of its capital) with the pyramiding principle of the holding company raised to an even higher power the capacity of the ultimately controlling equity to enhance its earning capacity. When the depression which began in 1929 cut down the earnings of the underlying operating companies, the essential financial weakness of pyramided finance capital was progressively revealed. It ended in widespread bankruptcies of holding companies and financial distress of their security holders.

The unregulated issuance of holding company securities made a mockery of the regulated issuance of operating company securities, to the extent to which such regulation had been carried by the states. Lack of uniform accounting and of accounting control rendered investment markets less efficient in the pricing function, if indeed these markets had not been deliberately rigged by fictitious purchases. Moreover, the lack of control over intercompany transactions made possible the marketing of holding company securities on the basis of fictitious asset values, thus burdening the operating companies with the support of overcapitalized financial structures. And, finally, the scattered and fragmentary holdings of operating companies in many cases brought no gains in managerial efficiency, which was the boast of the better integrated and co-ordinated holding company systems. It was the pressure to sustain a level of earnings to support these overextended financial structures in the face of demands for rate reductions from consumers in the emergency of a deepening depression which ultimately brought on political action in the shape of the federal act of 1935 to regulate the holding company.

In this act, the jurisdiction of congress was grounded upon interstate commerce and upon the use of the mails. A holding company was defined as one which controlled 10% or more of the voting stock of electric and gas utilities. All holding companies coming within the scope of the act were required to register on or before Dec. 1, 1935, with the Securities and Exchange commission (SEC) and to give certain relevant information. Failure to register meant the loss of mailing privileges and of the right to carry on interstate commerce.

In addition, certain specific provisions were included to eliminate designated evils. Henceforth, all holding company securities were subject to SEC control, as were the securities of operating subsidiaries. As to the latter, there were provisions safeguarding the jurisdiction of state commissions. Affiliated service companies were to be dissolved or transmuted into mutual companies. "Upstream loans" were forbidden. Intercompany transactions in securities and properties were subjected to commission control, as were interlocking directorates and officers. Pyramiding was limited to three tiers of companies (the grandfather clause) and the corporate structure was to be simplified, with voting power equitably distributed. The so-called "death sentence" provision made it the duty of the commission, as soon as was practicable after Jan. 1, 1938, to limit the operations of holding companies to a single integrated public utility system of functionally related properties. The passage of the act was followed by a sit-down strike of the holding companies which refused to register until the first constitutional test of the act in the Electric Bond and Share case in 1938. The defendant company denied the validity of the registration provision and sought a

declaratory judgment that the entire act was invalid.

The decision upheld the power of congress to require holding companies to register and to furnish the information required by the commission. The court also refused to render a declaratory judgment on the constitutionality of the act as a whole. On the other hand it sustained the position of the commission that, since the act provided for separability so that the invalidity of a part of the act would not render the whole invalid, the companies were free to challenge the remainder of the act when the commission's orders actually affected their interests. In short, the favourable decision overcame the reluctance of holding companies to register and put the SEC in a position where it could begin its real work of regulating holding companies.

Spurred on to new activity by this decision, the SEC proceeded with plans for seeking a voluntary integration into contiguous geographical units to facilitate the economies and improvements of service resulting from interconnection. Tentative plans were submitted by most of them. It was noticeable that companies were moving voluntarily toward simplification of corporate structures through the elimination of intermediate holding companies and toward the elimination of interlocking directorates. In the end, however, the results from these voluntary efforts proved to be disappointingly meagre. Accordingly, early in 1940, the SEC began its long-awaited action by issuing "show cause orders." Nine of the larger holding companies were required to file statements and plans as to their position and the steps to be taken in conforming to the provisions of the act. As stated, these limited operations to "a single integrated public utility system and to such other businesses as are reasonably incidental or economically necessary or appropriate to the operation of such integrated public utility system."

Corporate assets involved in these activities were estimated to exceed \$14,000,000,000. It was certain that these efforts on the part of the commission to make headway on its most important and difficult assignment would provide grist for its administrative mill for years to come. The details to be encompassed were technical in an engineering, legal and financial sense; they were individual to each property and the result of historical growth; they could be ascertained only upon painstaking investigation, because the facts were often obscure and their economic implications in relation to the legislative standard imposed were only dimly perceived by those who drafted the law and by its legislative sponsors. If the sprawling holding company systems operating through many states were to receive permission to operate more than one integrated system, they must be prepared to show that each additional system could not be operated as an independent system without loss of substantial economies, and that their common control did not impair localized management or the effectiveness of regulation. It was certain that the task would prove a severe test of the efficacy of the administrative machinery.

This outstanding issue of public policy finally came to a head when the North American Co. challenged the commission order directing the company to divest itself of all its other properties except those of its direct subsidiary, Union Electric company of Missouri. These properties were located in and around St. Louis, Mo., and in contiguous portions of Illinois and Iowa. The courts' answer to this challenge, in a long-delayed decision given in 1946, was unanimous and unequivocal. It declared that such regulation fell within the power of congress over interstate commerce and that the order did not violate

the due process clause of the 5th amendment. Since section 11b was the heart of holding company regulation, the SEC by this decision was given the green light to go ahead with its work.

Wartime Regulation of Utilities.—Regulation of U.S. public utilities during World War II fell into two periods: one beginning on May 29, 1940, with the Office of Production Management as the controlling agency, and a second beginning with the outbreak of war, under the general control of the War Production board.

The OPM operated through a Defense Communications board, a transportation division, a Heat, Light and Power division, the Federal Power commission, the Supply Priorities and Allocation board, and the Office of Petroleum Coordinator for National Defense. The major purpose of these agencies was to maintain contact with the war and navy departments, the maritime commission and all vital defense industries in order to translate their needs into public utility demands. In this connection it was important that the requirements in any area be anticipated and that steps be taken to meet them promptly. It was necessary to plan in co-operation with state and federal regulatory authority and with the utility industry for the most economical use of existing utility capacity, curtailment of civilian demands, emergency interconnections between systems and expansion of facilities. Where utilities were unable or unwilling to undertake the necessary construction, special arrangements were to be made through the president to finance or otherwise further such construction.

The same aims dominated the control exercised by the WPB. The agencies were reshuffled through the creation of the Office of War Utilities. In it a power division had jurisdiction over elective power, central steam heating and the production of power equipment. A communications division had jurisdiction over telephone, telegraph and cable utilities and the production of wire communication equipment. A gas division controlled natural and manufactured gas utilities and gas transmission lines, and a water division supervised water utilities. The significance of this regulation appeared from the fact that manufacture of a ton of aluminum required 20,000 kw.hr. of electricity, a ton of steel needed 14,000 gal. of water, the manufacture of a medium tank used 5,000,000 cu.ft. of gas, and the construction of a Victory ship required 63,000 telephone calls.

Regulatory procedure involved the issuing of general orders carrying the signature of the chairman of the War Production board and controlling the relevant activities of utilities affected. Administrative letters were used in interpreting and amending orders. By framing the initial orders in very general terms and modifying them by interpretations and amendments, the board kept control of ultimate decisions which could thus be adjusted to the trend of the war. In general, utilities were required to get authorizations before expanding their facilities. With the wartime demands for utility services, these facilities were used to full capacity and sometimes, especially in the case of electric power facilities, to the extent of overloading their rated capacity. The allocations and priority designations in the use of scarce war materials, especially steel, copper and aluminum, were accomplished through a system of certification.

At the peak of the war effort, U.S. power output had been increased by 69%, while installed generating capacity was increased by only 22%. This was reflected in a parallel

increase of the average annual plant capacity factor from 36.9% to 51.1%. Similar results were achieved in the use of gas, water and telecommunications services.

Another important means of meeting the emergency of around-the-clock operations was by expanding service interconnections where these were possible, thereby affecting an exchange of service so that work stoppages from breakdown in machinery could be prevented. In part the new construction was necessary to alleviate the hazard of numerous breakdowns of machinery caused by wear and lack of proper maintenance. The end of World War II made possible a speeding-up of the program of replacing the accumulated over-age equipment.

On account of the war emergency, the usual rule under which utilities served all customers was radically modified by the board. Customers engaged in nonessential activities did not need to be served at all, or their service could be curtailed if the additional load created too heavy a burden upon equipment or facilities. New service connections were scrutinized with care, because wire, pipes, poles were in short supply.

In the manufactured gas industry it became necessary, particularly in the east, to conserve gas because of the shortage of coal. Strict conservation programs were ordered into effect by the board in areas designated as critical. To alleviate these shortages, the construction of natural gas pipe lines was authorized, of which the Appalachian pipe line extending from Texas to West Virginia completed in 1944 was the most important. With its 1,200 mi. of 26-in. pipe, this was the longest natural gas line in the world. These emergency constructions were successful in reducing shortages and in bringing about a relaxation of restrictions even before the end of World War II.

During the war, telephone utilities were unable to meet the demand for service. In spite of a threefold increase in the production of communication equipment, the civilian supply was inadequate. Manpower shortages aggravated the problem. With the mass migration of the civilian population and the far-flung distribution of the armed service personnel, an unprecedented demand for toll service was created. Some new construction was authorized by the communications divisions to provide additional channels for toll messages with a minimum expenditure of critical materials. The use of coaxial cable, providing many more circuits than an equivalent amount of materials used in ordinary cable construction, was important in this connection. It was in local exchange service, therefore, that there was the largest backlog of unsatisfied demand at the close of the war. (See also TELEPHONE.)

On the whole, the 13,000 water utilities serving about 85,000,000 people came through the war period with the least strain on their facilities. Here and there, particularly in large metropolitan centres like New York city, N.Y., Philadelphia, Pa., Los Angeles, Calif., and San Diego, Calif., critical shortages developed which were alleviated by authorized expansion in facilities. Water shortages were not generally susceptible of correction by interconnection. Only an expansion in primary supply or in storage facilities could be of genuine help. To this end, more concrete storage tanks were authorized instead of steel tanks, and an extensive campaign of voluntary water conservation was initiated, particularly in the reduction of waste from some 150,000,000 leaking water fixtures.

Similar voluntary conservation campaigns were carried out by the telephone and electric power industries. These

endeavours were supplemented by conservation orders such as the "brownout" put into effect from Jan. to May 1945. "War time," in effect since Feb. 6, 1942, was calculated to save approximately 1,000,000 tons of coal annually and to make unnecessary the installation of an additional 1,000,000 kw. of new generating capacity.

The WPB thus was able to meet all war requirements without undue hardships upon the civilian population; it received less criticism than other wartime regulating agencies. It began to relax its controls and prepared for its discontinuance by Oct. 1, 1945.

In general, the OPM and WPB supervised the utility industry from the point of view of the supplying of service and the allocation of physical materials. Price rationing was at first left to the normal functioning of the civilian regulating agencies whose co-operation was, of course, freely forthcoming. To extend price rationing and service rationing to the wide field of civilian supply where shortages were critical or impending, congress finally set up the Office of Price Administration. Legislatively, this was the most significant event, for from Oct. 2, 1942, it became the duty of this agency to "aid in stabilizing the cost of living." This was the incidence of OPA's activities upon the utility industries. Legislation placed the OPA in a position where it might influence the rate-making activities of regulating commissions. Under the terms of this act, OPA had to be notified 30 days in advance of a rate proceeding and given an opportunity to intervene in any case involving rate increases by a public carrier or other public utility. This power to intervene was upheld by a U.S. circuit court of appeals in the case of an interstate motor carrier on the ground that the Interstate Commerce act had been superseded "to whatever extent may be necessary to achieve its own purposes."

Early in 1943, with the placing by executive order of local electric railway and motor bus services under the control of the Office of Defense Transportation (already in charge of all forms of interstate transportation) and with the merging of the control of all nontransport utilities under the revised WPB setup, the dual system of wartime regulation under the war powers and of regulation under the police powers and their federal equivalents was simplified.

The most significant single instance of OPA effect on public utility regulation was the reduction in freight rates ordered by the ICC in April 1943. This reduction removed increases of 6% which the commission had granted early in 1942. In carrying out the purposes of the stabilization act of Oct. 1942, the commission found that the passenger rate advances of 10% did not need to be disturbed, and that despite the freight rate decreases the resulting service revenues would be sufficient to meet all costs. Similarly, OPA sought to prevent increases in other public utility prices, especially those which flowed automatically from contractual or technical requirements like the various types of fuel clauses.

In spite of OPA pressure, however, rate increases were granted when it became necessary to provide increased revenues in order to keep up good service. With the close of the war in 1945 and the sloughing off of the powers of OPA in 1946, regulation of utilities once more returned to the civilian agencies. (M. G. G.)

Public Utilities in Other Countries

Electricity.—In Great Britain the year 1937 marked an interesting stage in the story of public electricity supply. A clear decade had then passed since the formation of the Central Electricity board (C.E.B.), late in 1926. In 1927

its program was planned and announced; by 1937 it was practically completed, and the grid, interconnecting the principal generating points of the whole country, had been trading three years and in full operation for a year.

The total output of electricity from public supply stations in 1937 was 22,905,000,000 units. At the end of that year the grid system comprised approximately 4,180 mi. of transmission lines, 2,938 of which operated at 132,000 volts, and the maximum demand on the grid was 5,967,000 kw. The number of selected stations was 137, with a total installed capacity of 7,653,570 kw.

At the close of 1945, the corresponding figures were 5,158 mi. of transmission lines, 3,626 operating at 132,000 volts; there were 142 selected stations with a total installed capacity of almost 11,500,000 kw. Output of public electricity supply in 1945 was 57% higher than in 1938, the last complete year before World War II.

Under the threat of war the C.E.B., as a precautionary measure, prepared a scheme for establishing a reserve of mobile plant, also a "pool" of switchgear, transformers and other equipment which was stored in various places throughout the country. On many occasions apparatus was withdrawn from the pool and made available for temporary use in the prompt restoration of essential supplies.

The six years of war proved to be eventful indeed to the more vulnerable centres of generation, and often, under imminent danger of fire and explosion, supply that had been interrupted was resumed within a matter of hours by heroic efforts on the part of officials and staff. The power station at Fulham, London, suffered a direct hit on Sept. 9, 1940, and 190,000 kw. of plant was put out of action; yet in a few hours local services were in operation from the grid, substations and transformers having remained undamaged. During the battle of Britain, damage from bombs and from the trailing cables of escaped barrage balloons rose to a maximum.

The value of the grid was amply proved. Thanks to its existence, new factories in the safer areas could be erected in the knowledge that electrical power would be available.

The need for postwar planning caused a change in the attitude toward plant replacement. Normally the average life of generating machinery was taken as 20 years. By the winter of 1946-47, no less than 2,000,000 kw. of existing generating plant would have exceeded that term. The difficulty of replacing so large an amount, together with the construction of new plant to meet future expansion of demand, was obvious; the C.E.B. therefore assumed, in order to form a program, that an extension to 25 years would be reasonable and safe.

The question of nationalization, which became prominent during 1945 and 1946, had led to the tabling of a government bill at the beginning of 1947.

In the British commonwealth, the shortage of supplies caused by the war produced serious problems in other parts of the world. Overworked and undermaintained plant occasionally failed; machines ordered from Britain were not only delayed, but also sometimes lost at sea. Nor did difficulties cease with the end of hostilities.

All Australian undertakings experienced great difficulties in obtaining additional plant and material to meet the heavy demands of war, yet carried on with remarkable success. The State Electricity commission of Queensland, which had many of its smaller generating centres adversely affected, developed its sales from 148,000,000 units in 1937 to 269,000,000 units in 1942. Hydroelectric possibilities were being studied in north Queensland, the Land and Water Resources Development act of 1943 having con-

London repair squad working on a broken gas main beneath the pavement, after a bombing raid over the city during World War II

stituted a board of investigation for that purpose. Other acts were passed later providing for the reorganization of supply on the basis of regional development boards. At the end of 1946 there was, however, an urgent need for increased generating facilities.

The total connected load in relation to hydroelectric development in New Zealand increased from 2,152,201 kw. in 1940 to 2,814,103 kw. in 1943; the number of consumers from 426,354 to 460,771. In both islands the growth of secondary industries made necessary by the war was a factor in the increased demand. Of the total of 40 main stations, 32 were water-power, seven oil-engine driven, and one was a steam station.

In Tasmania, units generated in 1942 totalled 698,000,000, in 1944 738,000,000. Approximately 85% of the homes in Tasmania were supplied with electricity, and there was every reason to anticipate the establishment of new industries and the expansion of existing ones; but fluctuations in the available labour force proved a hindrance to the rapid progress of the program of constructive work.

The Electricity Supply commission of South Africa, established in 1923, moved in Aug. 1936 into its own building, Escom house, Johannesburg, which was officially opened in June 1937. Supply had begun in the previous year from the new Klip power station (the largest steam station in the southern hemisphere), and the great expansion of the gold mining industry at that time created a heavy demand. The loss of essential generating plant at sea hindered completion of extensions that had been begun in 1939, and the end of hostilities found power supply activities severely handicapped by shortage of generating capacity and distribution equipment. The commission in 1946 owned approximately 2,685 route mi. of transmission

678 lines and cables, and its licensed area of supply throughout the union covered about 34,369 sq.mi. A new record total of 4,861,000,000 units generated from the various power stations was established in 1945, exceeding by 7% the previous year's total. Bulk supplies for mining, etc., represented practically the whole output of the Klip and Vaal power stations and a large proportion of that of Witbank station. In 1946 an extension of railway electrification in the Capetown district was planned.

In Canada, taking a report of the Hydroelectric Power commission of Ontario alone, the total energy output handled by the commission in 1945 was 65% greater than in 1938, and the total energy production from all sources was nearly 12,500,000,000 kw.hr. In the years 1936-40 the commission actually constructed 9,373 mi. of rural primary line to serve a total of 55,000 consumers. This progress in rural electrification greatly benefited food production during the critical war period. Between 1941 and 1944 the restrictions on the use of materials stopped all further rural extensions, but in 1946 they had been actively resumed, and rates to rural consumers had been reduced. In 1944 a scheme of reducing the wholesale cost of supply to certain municipalities by means of a small levy per horsepower was successfully put into effect. An important development was the installation of 6 generating units with a total capacity of 360,000 h.p. on the Ottawa river, with the object of increasing the power resources of the southern Ontario system; for this project 235 mi. of transmission lines were required.

In India a Central Technical Power board had been established to initiate, co-ordinate and promote electrical power development throughout the country, in consultation with the provincial and states governments. It was also to organize research into electricity supply and carry out testing and standardization, encourage education and propaganda and in general promote the greater utilization of electricity.

(W. L. R.L.)

Gas.—In 1937 the gas industry in Great Britain and most European countries was largely composed of independently operated local units, each manufacturing and selling gas and its by-products in a single city, town or village. Local manufacture had been abandoned only where bulk supplies of gas were available at low cost as a by-product of coke ovens serving the steel industry (notably in Germany and Belgium) or from comparably large installations set up by the gas industry. Rising coal prices and wages, however, stimulated the use of mechanized plant in gasworks, which could most advantageously be employed at large works well situated for the receipt of coal and the dispatch of by-products. This encouraged the closing down of the smaller works and the laying of transmission mains to the districts previously supplied by them. Similar considerations prompted the further exploitation of surplus gas from the coke industry. These developments were for the most part sporadic, expansion outwards from the larger centres of production occurring piecemeal. They were practicable only where the demand in the adjacent areas and the relative cost of large-scale against local production justified transmission costs.

The decline of gas lighting was more than compensated for by developments in domestic cooking, water heating, refrigeration and space-heating loads. In the design of equipment, the trend was toward economy in consumption, improvement in appearance and, in the case of cookers, ease in cleaning. In the industrial field World War II provided added stimulus to the development of

Reconstruction work on the war damaged Leningrad gas works. Supply lines to industrial plants and apartment houses were established while work was still in progress

specialized appliances for process work; radiant heat, for example, was used for drying in line production. Gas was increasingly used in the preparation of foodstuffs, particularly in breadmaking, and for central heating in large buildings. In Britain, progress was made with the use of gas coke in domestic solid-fuel smokeless grates. The most significant development in the demand for by-products arose from the use of phenols and cresylic acid by the rapidly developing plastics industry.

The technical advances during 1937-46 resulted in a change in the political aspect of ownership. Where the advantages of centralized production could be realized, the purely local unit tended to be replaced by the large-scale undertaking formed by amalgamation under company or municipal aegis, while holding company groupings were an alternative to the same end. In postwar Europe, however, this trend gave rise to political proposals for na-

tionalization (hitherto adopted only in the U.S.S.R.) and in the case of France the state assumed control in 1946.

Water.—Before World War II, most water authorities in Great Britain were concerned with the need for extending and improving their works in view of the continuing increase in consumption, and many notable schemes were in course of construction. The Durham County Water board inaugurated the Burnhope reservoir; construction of the London Metropolitan Water board's three new reservoirs in the Thames valley and the Lee valley had started but was subsequently held up; Manchester corporation completed a masonry dam of novel design at Haweswater; and, among others, new reservoirs were being built at Ladybower and Fernworthy for the Derwent Valley Water board and Torquay corporation respectively. Several large schemes for supplying water to rural areas were also in hand.

With the outbreak of World War II, schemes on which building had not yet started were postponed; where it was necessary to meet additional wartime requirements, others were allowed to proceed, but progress was generally slow. In the so-called "safe areas," numerous authorities which had hitherto found themselves adequately supplied, were suddenly confronted with considerably increased calls on their resources, for reasons connected with war production and the requirements of a temporarily increased population. Supplies had to be restricted or temporary schemes put into operation. In vulnerable areas, special attention was directed to the protection of plant and buildings; improvements were carried out to distribution systems and the location of valves and hydrants; static water tanks for fire-fighting purposes were provided in thousands to augment the supply from mains, and alternative sources of supply were prepared. Adequate and reliable sterilization equipment was kept ready for use whenever the supply of water through repaired mains was resumed after aerial attack. Thanks to these precautions no serious epidemic attributable to the pollution of water occurred throughout the war. To meet the needs of the fighting forces in the field the provision of a safe supply of water, at short notice, was of paramount importance, and most efficient portable distilling and filtering plants were manufactured in large quantities. A noteworthy achievement was the successful development of a simple chemical process and small apparatus for producing drinking water from sea water. It saved the lives of countless airmen and shipwrecked sailors.

In 1944 parliament passed the Rural Water Supplies and Sewerage act, whereby water contractors and county councils were to take steps to provide piped supplies, if reasonably practicable, to all houses and schools in rural

areas. Toward the cost of construction the minister of health was empowered to make grants—conditional upon similar grants by the county councils—up to a total sum of £100,000,000. In 1945–46, numerous rural supply schemes were prepared but very little construction was begun. The Water act, 1945, laid down the procedure under which the minister of health assumed the responsibility for the conservation and proper use of the country's water resources and supplies. The government policy was to eliminate small water supplies and works, and where advisable, to set up water boards and to effect amalgamations. Many such proposals were under consideration.

In Europe World War II brought havoc to many waterworks. The Moehne and Eder dams in Germany and the Tirso dam in Sardinia, among others, were partially destroyed by bombing. The last mentioned was the highest multiple arch dam in Europe. Soviet Russia suffered severely, particularly during the German retreat, and many splendid waterworks, among them the Dnieprostroi, were wrecked. The preparation of new schemes began in 1944.

In India considerable attention was directed to the improvement of water supplies and modern schemes were in course of development for all places with a population of 10,000 persons and over. The supply for Calcutta was to be increased to 300,000,000 gal. per day. A scheme for conveying more than 3,000,000 gal. per day from the Murray river, Australia, through 223 mi. of concrete-lined steel pipes to Whyalla was completed in 1944. Further works were also being planned for augmenting the supply to Durban (S. Africa), involving the construction of a large concrete dam, and two schemes were envisaged at Table mountain to yield a supply of 55,000,000 gal. per day. Puerto Rico

An unincorporated territory of the United States directly under control of congress, Puerto Rico is approximately 1,600 mi. south by east of New York city, 1,000 mi. east by south of Florida and 500 mi. north of Venezuela. The pop. by 1940 census was 1,869,225 (whites, 76.2%;

Negroes, 23.8%) and was est. at 2,101,698 in 1946. The executive head or governor is appointed by the president of the United States. Heads of the insular government's seven departments (education, justice, health, interior, treasury, agriculture and commerce, and labour) act as a cabinet, appointed by the governor except for the first two, who are appointed by the U.S. president. The insular legislature consists of 19 senators and 39 representatives elected by Puerto Ricans every four years.

In the last year of the decade 1937-46 two events of major importance to the island's drive toward eventual self-government, promised to aid in the solution of the vital question of Puerto Rico's ultimate political status. The governor, Jesus T. Pinero, who was inaugurated on Sept. 3, 1946, was the first native-born Puerto Rican to hold this post in the entire history of the island, under either Spanish or U.S. control. His appointment by Pres. Truman was considered an important step toward greater Puerto Rican autonomy. Previously, in Oct. 1945 Pres. Truman had recommended to congress that it enact legislation to submit various alternatives of ultimate political status to the people of Puerto Rico in order to ascertain what the people themselves desired most for their political future.

Economic and Industrial Progress.—One of the most densely populated areas in the world, with more than 600 persons per sq.mi., Puerto Rico continued to suffer from chronic unemployment. With an agrarian economy, plus the fact that almost one-half of the island is mountainous, about two-thirds of the island's population had, by U.S. standards, a low level of living. To counteract this economic unbalance, constantly increasing federal government assistance was essential, particularly in the decade 1937-46.

Puerto Rico received the full impact of the world-wide depression of the 1930s, and to aggravate the island's plight, it had been devastated by two hurricanes (in 1928 and 1932), striking within four years of each other. In 1935, on Pres. Roosevelt's recommendation, the congress appropriated \$24,000,000 to set up the Puerto Rican Reconstruction administration. Later appropriations brought the total to about \$76,000,000.

This agency aimed primarily to improve the condition of rural workers and small farmers in the sugar industry and to effect economic renovation of coffee and tobacco areas. No added funds were appropriated for P.R.R.A. after 1940, but P.R.R.A. had assisted the island through a very difficult period of economic stress, and many basic improvements to the economy of the island were effected.

In 1939 the Works Progress administration was extended to Puerto Rico and operated from Sept. 1939 until Dec. 1943, six months after it had been discontinued in the United States. Although it lacked an over-all reconstruction program, WPA had a case load of 40,000 Puerto Ricans on its pay roll, using their services for useful projects. One of its most important contributions was the institution of the school lunch in Puerto Rico. Operating in conjunction with the food distribution administration and the department of education, WPA by 1943 was serving lunch five days a week to almost 200,000 children, many of whom would have been badly undernourished without it.

World War II immediately affected Puerto Rico's food supply and employment problems adversely. The German submarine campaign in the South Atlantic began a month after Pearl Harbor and established a stringent import and export blockade. Since the island imports its staple items of

diet—rice, beans, meat, potatoes, codfish, flour, butter and lard,—an acute food shortage and even starvation for thousands were threatened. Co-ordinated action by the U.S. departments of the interior and agriculture and insular government averted severe suffering for the people.

The blockade augmented unemployment by withholding from insular industries mechanical equipment and raw material, the greater part of which came from the United States. The needlework industry was at a low point during the greater part of the war.

When the emergency need for industrial alcohol compelled suspension of liquor manufacture in the United States, however, Puerto Rican rum found an enormously expanded market, profitable not only to the local distillers but also to the insular government, since the Organic act provided that federal revenue taxes collected on island products be returned to the Puerto Rican government.

Significant social and economic reforms and improvements were put into effect in the decade. The Puerto Rican legislative sessions of 1941 and 1942 together set up the planning board, the land authority, the Puerto Rico Industrial Development company, the Puerto Rico Development bank and various other reform agencies.

Social and Cultural Progress.—Puerto Rico had become outstanding, among areas comparable in size and resources, in the type of laws enacted by its legislature, especially those put into effect within the ten years 1937-46. The legislation indicated a desire for comprehensive local improvement and stressed social advancement. In 1936 alone, acts approved had included: provision of hospital aid to war veterans, share croppers law, law to protect new industries, weights and measures standard law, fishing industry law, income tax law, public works law, law on prohibition of child labour and the staple food price-control law. This type of legislation, together with foresightedness of political leaders, was credited for the constantly elevating commercial, educational and social relations with the mainland. When Puerto Rico came under the jurisdiction of the United States, 77.3% of the people were illiterate. There were very few schools or educational institutions of any kind. Rapid advances in the public school system, educational methods and techniques lowered the rate of illiteracy to somewhat less than 31.5% by 1940.

Puerto Rico had developed an elementary vocational rural school, known as the second-unit school, that was being adopted in Latin American countries having similar educational problems. It provided a combination of academic and vocational training for rural children through the sixth grade, and also served as an education and cultural centre for both parents and children. The schools directed their programs chiefly toward the community, its problems, activities and resources. Training in agriculture, carpentry, repair work, cooking, care of children and health education were stressed. A social worker, attached to each school, worked with the families of the community.

The University of Puerto Rico, modelled along universities in the United States, was adapted to the particular needs of the island. With Puerto Ricans keenly aware of the advantages of higher education, the university's enrolment steadily grew to more than 4,000 full-time students in 1946.

The university was engaged in research work aimed at the solution of problems directly affecting the island. It carried on extended social research to discover how best to improve economic and social conditions in Puerto Rico. During the decade, the institution became more and more a central meeting place for exchange of ideas on continental and Latin-American cultures. Annually, lecturers, pro-

Caribbean drydock for the U.S. navy near San Juan, Puerto Rico, as it appeared under construction in 1940. The \$3,000,000 dock was designed to receive ships drawing up to 29 ft. of water

fessors and students from various countries in North, South and Central America, visited the university, and in turn, representatives of the university regularly went abroad to study and teach.

Wartime and Postwar Progress.—The military fortification of Puerto Rico began in 1939 with the growing threat to world peace. Airfields were constructed in various parts of the island, roads were built, and San Juan was armed

against attack. With U.S. entrance into World War II, the tenth naval district, with headquarters in San Juan, was declared a front line, combat area. Throughout the war, large numbers of continental and Puerto Rican troops were stationed in the island.

Puerto Ricans entered every branch of the service. While some Puerto Rican troops went to the Pacific and to the European theater of operations, others guarded the Canal Zone and the general Caribbean area.

Many of the 60,000 young Puerto Ricans who saw action never had seen life beyond the shores of the island.

They returned with a knowledge and appreciation of life in the United States, in Italy, France, Germany, China, Japan and India. They brought back to their island ambitions and ideas for its improvement, engendered and fostered by their travels.

The decade, finally, saw tremendous expansion of air transportation facilities in Puerto Rico. In 1945 the civil aeronautics board approved applications for routes to Puerto Rico by four major airlines, and several lines began to operate. Puerto Rico's capital, San Juan, became one of the nation's important airports.

Pulitzer Prizes

Pulitzer prizes "for exceptional achievement in journalism and letters," to be awarded annually, were set up by the will of Joseph Pulitzer, publisher of the *St. Louis Post-Dispatch* and the *New York World* and founder of the Columbia university school of journalism. Awards were to be made by the trustees of Columbia university on the recommendation of the Advisory board of the graduate school of journalism.

At the end of the decade, all awards were valued at \$500. Prior to 1942, prizes in the letters division and in the local reporting category of the journalism division were \$1,000. Between 1937 and 1946 four new award categories were set up. In three of these—news photography, national telegraph reporting and international telegraph reporting—awards were made for the first time in 1942. The fourth, in the field of musical composition, was first announced in 1943.

Awards for distinguished examples of newspaper cartoonists' work were made to the following artists: 1937, Clarence Daniel Batchelor; 1938, Vaughn Shoemaker; 1939, Charles G. Werner; 1940, Edmund Duffy; 1941, Jacob Burck; 1942, Herbert Lawrence Block; 1943, Jay Norwood Darling; 1944, Clifford K. Berryman; 1945, Bill Mauldin; 1946, Bruce Alexander Russell.

Pulitzer prizes in letters were awarded in five classifications: the novel, the drama, history, biography and poetry.

For distinguished novels, prizes went to the following works and their authors: 1937, *Gone with the Wind*, by Margaret Mitchell; 1938, *The Late George Apley*, by John Phillips Marquand; 1939, *The Yearling*, by Marjorie Kinan Rawlings; 1940, *The Grapes of Wrath*, by John Steinbeck; 1941, no award; 1942, *In This Our Life*, by Ellen Glasgow; 1943, *Dragon's Teeth*, by Upton Sinclair; 1944, *Journey in the Dark*, by Martin Flavin; 1945, *A Bell for Adano*, by John Hersey; there was no award in the novel category in 1946.

For original American plays considered to represent the educational value and power of the stage, prizes were awarded to eight dramatic productions and their authors: 1937, *You Can't Take It with You*, by Moss Hart and George S. Kaufman; 1938, *Our Town*, by Thornton Wilder; 1939, *Abe Lincoln in Illinois*, by Robert E. Sherwood; 1940, *The Time of Your Life*, by William Saroyan; 1941, *There Shall Be No Night*, by Robert E. Sherwood; 1942, no award; 1943, *The Skin of Our Teeth*, by Thornton Wilder; 1944, no award; 1945, *Harvey*, by Mary Chase; 1946, *State of the Union*, by Howard Lindsay and Russell Crouse.

Ten historians received prizes for distinguished books on U.S. history: 1937, *The Flowering of New England*, by Van Wyck Brooks; 1938, *The Road to Reunion—1865–1900*, by Paul Herman Buck; 1939, *A History of American Magazines*, by Frank Luther Mott; 1940, *Abraham Lincoln, The War Years*, by Carl Sandburg; 1941, *The Atlantic Migration, 1607–1860*, by Marcus Lee Hansen; 1942, *Reveille in Washington*, by Margaret Leech; 1943, *Paul*

Revere and the World He Lived In, by Esther Forbes; 1944, *The Growth of American Thought*, by Merle Curti; 1945, *Unfinished Business*, by Stephen Bonsal; 1946, *The Age of Jackson*, by Arthur Meier Schlesinger, Jr.

For distinguished U.S. biographies, prizes were awarded to 11 writers: 1937, *Hamilton Fish*, by Allan Nevins; 1938, *Pedlar's Progress*, by Odell Shepard, and *Andrew Jackson*, by Marquis James; 1939, *Benjamin Franklin*, by Carl Van Doren; 1940, *Woodrow Wilson, Life and Letters*, vols. vii and viii, by Ray Stannard Baker; 1941, *Jonathan Edwards*, by Ola Elizabeth Winslow; 1943, *Admiral of the Ocean Sea*, by Samuel Eliot Morison; 1944, *The American Leonardo, the Life of Samuel F. B. Morse*, by Carleton Mabee; 1945, *George Bancroft: Brahmin Rebel*, by Russel Blaine Nye; 1946, *Son of the Wilderness*, by Linnie Marsh Wolfe.

In the field of poetry, nine writers were awarded prizes: 1937, *A Further Range*, by Robert Frost; 1938, *Cold Morning Star*, by Marya Zaturenska; 1939, *Selected Poems*, by John Gould Fletcher; 1940, *Collected Poems*, by Mark Van Doren; 1941, *Sunderland Capture*, by Leonard Bacon; 1942, *The Dust Which Is God*, by William Rose Benét; 1943, *A Witness Tree*, by Robert Frost; 1944, *Western Star*, by Stephen Vincent Benét; 1945, *V-Letter and Other Poems*, by Karl Shapiro; 1946, no award.

Pulitzer Prizes for distinguished musical composition by Americans were given to four composers: 1943, William Schuman; 1944, Howard Hanson; 1945, Aaron Copland; 1946, Leo Sowerby. In 1944, a special award was made to the musical play, *Oklahoma!*, by Richard Rodgers and Oscar Hammerstein, 2nd. (See also LITERARY PRIZES; NOBEL PRIZES.)

Pyle, Ernest Taylor

Pyle (1900–1945), U.S. newspaperman, was born Aug. 3, 1900, on a farm near Dana, Ind. He studied at Indiana university but left a few months before graduation to become a reporter for a small town newspaper. He was copy editor for the *Washington Daily News*, 1923–26, and aviation editor for the Scripps-Howard papers from 1928 to 1932. Wearying of editing, he acquired a roving assignment and his daily experiences supplied material for a column which appeared in 200 newspapers. His simple human touch won a wide following, and thousands of readers shared in the restless wanderlust of the writer. When World War II started, he went to England; his vivid eyewitness descriptions of how Londoners were enduring the German air blitz established his reputation as one of the foremost U.S. war correspondents. From England he went to North Africa, where he lived in foxholes with the ordinary U.S. soldier. His columns, interpreting in simple language the fears, hurts and loneliness of the soldiers, established a link between the G. I. and his family back home. His coverage of the campaigns in North Africa,

Sicily, Italy and France brought him the Pulitzer prize in 1944 and several other newspaper awards. Fighting men looked upon him as their friend, and officers regarded him as a great morale-booster. In the fall of 1944, he apologetically withdrew from the war front to return home for a rest. Compilations of his columns appeared in book form: the first, *Ernie Pyle in England* (1941), was followed by two best sellers, *Here Is Your War* (1943) and *Brave Men* (1944). After a brief stay in the United States, Pyle was compelled by a sense of duty to return to the war—this time in the Pacific. He covered the Iwo Jima campaign, moved on to Okinawa with the marines and then to nearby Ie Island. There, at a point where all Japanese opposition seemingly had been overcome, he was killed by machine-gun fire, April 18, 1945.

Pyrite

The peak of pyrite output during World War II was 9,900,000 short tons in 1942 and 1943, as compared with 11,000,000 in 1937 and 1938; after 1943, output declined sharply.

In the United States, an increase of 40% in pyrite production between 1937 and 1943 failed to offset declines in imports, leaving a 5% decrease in the available supply. Transportation difficulties gradually cut imports from Spain almost to nothing, and the increasing supplies from Canada failed to meet the deficit in the Spanish shipments. In 1937 the available supply included 53% of domestic origin, 43% from Spain and 2% from Canada; in 1942 the corresponding figs. were 71%, 2%, and 28%. Between 1943 and 1945, the United States output declined 10%, and imports dropped 27%, a decrease in available supply of 14% as compared with 1943, and of 18% as compared with 1937. Since about three-quarters of the total sulphur from all sources continued to be used in the production of sulphuric acid, it was pertinent to note the increasing amount of acid produced from roaster gases at copper and zinc plants treating sulphide ores. This source of sulphur was almost as large as the pyrite output itself.

The Canadian output increased more than three-fold, the greater part of which was exported to the United States, largely but not entirely replacing the imports no longer accessible from Spain. (See also SULPHUR.)

Quartz Crystals (Radio)

The enormous increase in demand for radio-grade quartz crystals which resulted from World War II found the United States unable to produce more than insignificant amounts—5,800 lb. in 1943 and 3,934 lb. in 1944. Although small amounts were imported from other sources, Brazil was almost the sole source of supply. The effect of war demand may be traced in the following data:

	Imports,* lb.	Consumption, † lb.	Finished crystals produced, lb.
1937	32,821	?	?
1938	56,171	?	?
1939	67,052	?	?
1940	126,521	31,000	?
1941	2,237,608	59,000	?
1942	2,612,106	682,000	6,888,000
1943	3,356,000	1,588,000	22,575,000
1944	2,300,506	1,858,000	29,939,000
1945	1,329,798	1,040,000	18,918,000

* Includes optical grades.

† Radio grades only.

The demand for radio quartz was so great that during the height of German submarine activities, the crude crystals were flown from Brazil to the United States in planes. With improved cutting efficiency, the use of smaller sizes, and the development of methods for rehabilitating imperfect plates, the number of plates cut from a lb. of crystal increased from 9.5 in 1942 to 18 in 1945. The transportation load was reduced by more careful inspection and rejection of unsuitable crystals before shipping from Brazil.

In 1944 there were 113 companies cutting quartz crystals in the United States, of which possibly not more than 20 were required for postwar needs. (G. A. Ro.)

Quebec

The Canadian province of Quebec occupies most of the lower basin of the St. Lawrence river, but its northern wilderness of Ungava extends to 60° 40' latitude. Its southern boundary is mainly based on the 45th parallel, bordering New York, Vermont and New Hampshire; while to the southeast and east it adjoins New Brunswick, and to the west Ontario as far as 79° 33' longitude. Its land area is 523,860 sq. mi., of which only the southern one-third is populated. The capital is the city of Quebec (pop. 1941-150,757); other cities are Montreal (903,007, greater Montreal 1,139,921), the largest city in Canada; Trois Rivières (42,007); Sherbrooke (35,

Spillway supplying 540,000 h.p. to an aluminum plant near Arvida, Quebec, where increased wartime demands for aluminum speeded completion of hydroelectric power developments on the Saguenay river

956); and Hull (32,947). Both the French and English languages are legal, but the French language is used by the greatly predominant population of French origin. The provincial government is affiliated with the Roman Catholic Church, and 86.9% of the people are Catholics; but all religions are tolerated, and other percentages are Anglicans 4.9, United Church 3.0, Hebrews 2.0 and Presbyterians 1.7. The 1941 Dominion census gave the population of the province as 3,331,882, of which the French race had 2,695,000, the British races 452,887, the Hebrew race 66,277 and the Italian race 28,051. The French race in Canada as a whole totalled 3,483,038, or 30.27% of the population of Canada, and outside of Quebec is situated largely in adjoining New Brunswick and Ontario. On account of its high natality the population of Quebec showed a decennial increase of 15.90% in 1941 as compared with 10.89% for Canada as a whole, and its cities also increased more rapidly than those of other provinces.

National Union Government—First Phase.—The Liberal party controlled the provincial government of Quebec for 39 years up to 1936; and its leaders, especially the last premier, Alexandre Taschereau, were not adverse to industrial development by English-speaking Canadian and U.S. large business interests. A dissident group known as Na-

tional Action Liberals challenged this co-operation in the name of French-Canadian nationalism. During the depression the Conservative dominion government had asserted centralized authority by a series of "New Deal" directed economy laws trenching upon the provincial rights set forth in the British North America act of 1867, to which the people of Quebec were attached because of the special status in the dominion which it gave them. When the new Liberal government at Ottawa in 1936 showed a tendency to continue the centralizing policy at the expense of the authority of the provinces, the opposition party in Quebec, theoretically Conservative and led by the able Maurice Duplessis, had a popular issue against the Liberals in Quebec. In alliance with certain National Action leaders it formed the National Union, and aided by hard times it pressed charges of corruption, non-nationalism (French-Canadian) and abandonment of provincial privileges. Forcing an election in Aug. 1936, Duplessis overthrew the Taschereau administration, taking 76 of the 85 seats in the Quebec parliament.

Premier Duplessis' supporters at this stage included many advocates of the complete separation of Quebec from the Dominion, with the establishment of a French-Canadian republic, "Laurentia." He sanctioned a law making the French language predominant in the interpretation of provincial statutes. When Prime Minister King at Ottawa appointed the Rowell commission to study a revision of the British North America act toward centralization, Duplessis announced that the Quebec government would not recognize the commission and that any attempts at centralization would meet fierce resistance. Another group of his supporters had strongly fascist aims, including the "nationalization" by the province of large industrial enterprises, the formation of labour and other guilds, and the institution of a corporative government; so that his regime gained the reputation of being National Socialist or semi-totalitarian.

At this time C.I.O. organizers, mainly from the United States, were conducting a campaign to unionize labour in Quebec and elsewhere along communistic lines, and in repressing them Duplessis was able to gratify his authoritarian followers to some extent. In March 1937 his parliament passed a so-called "Padlock Law" permitting provincial officers to close any premises used for socially subversive gatherings or propaganda; and throughout the year it was used with Draconian severity. When the success of certain C.I.O. strikes showed that labour was in reality restive, Duplessis passed a Workmen's Wages act, providing for the establishment of standard labour conditions by direct agreements which the government would enforce and generalize. Again late in the year, when stern measures against agitators seemed likely to raise antagonism, the Fair Wages board which Duplessis had created in the summer handed down awards of wage increases on a large scale for all workers. The firm policy toward radicalism pleased the Catholic Church, the official religion of the province, which was promoting unions under its own auspices. It also pleased the big industrialists, and Duplessis' relations with them became better than his ultranationalist adherents could brook; so that when he declined to press for the socialization of utility enterprises he was deserted by several prominent political leaders.

The second congress of French language groups in North

America was held at Quebec in 1937, with the presence of Gov. Leche of Louisiana as well as Louis Bertrand of the Académie Française. Another development was the founding of a formal Fascist party of Quebec by M. Adrien Arcand, regarded as an associate of Duplessis. It advocated the usual fascist doctrines, and opposed Semitism, Masonry and democracy. For a time its existence caused Duplessis himself to be regarded as semi-fascist, but in 1938 it suffered scissions, joined with similar parties in the prairie provinces and gradually disintegrated. It had some support among the clergy; but in general there was more clerical interest in French-Canadian nationalism, involving the expulsion of Anglo-American interests from businesses utilizing the natural resources of the province. Abbé Lionel Groulx, of the University of Montreal, a gifted intellectual, was conspicuous in this movement in 1938, but the clergy did not advocate the withdrawal of the province from the dominion or empire.

A curious alliance grew up in 1938 between Duplessis and the independent-Liberal Premier Hepburn of Ontario. Both premiers were opposed to constitutional reforms which might sap provincial authority, since their provinces were wealthier than the other seven provinces and would furnish the largest share of the tax funds from which national social experimentation would be financed. They also objected to the St. Lawrence waterway project, which might weaken Montreal as a port and take hydro-electric power from Ontario; and they favoured high tariffs because of their manufactures. They wished to be permitted to export electric power to the United States, which Ottawa felt would cause international complications.

Evidence of racial particularism appeared in 1938 in the wide celebration in Quebec of the centenary of the Papi-neau rebellion of 1837-38, regarded as the origin of self-government for the Canadian provinces. Evidence that Duplessis was able to co-operate with big business was afforded by the inauguration of the Baie Comeau paper mills created by the Ontario Pulp and Paper company in conjunction with the McCormick interests of Chicago.

Liberal Victory.—When World War II broke out in the summer of 1939, there was question as to how French-Canadian sentiment would react, not only because of the Anglo-Saxon issue but because of the emergency powers which the Dominion assumed to meet the crisis. Duplessis confidently called new provincial elections on an anti-war platform in the early autumn. The result showed that he had overestimated the influence of the fascist and nationalist orators and writers; the Liberals won 68 of the 85 seats. The people felt an attachment to the British monarchs, who had visited the province in the spring; and they had been reassured in advance by Prime Minister King and his minister of justice, Ernest Lapointe, that they would have full voice in any war decisions made by the Dominion. The new Quebec government, headed by Adélard Godbout as Liberal premier, at once manifested a spirit of co-operation with the dominion Liberal government. A Canadian supreme court decision in Jan. 1940, negating the right of England to dominate Canada, was also gratifying to Quebec opinion.

At the time of the dominion national elections of March 1940 French Canada was again promised by King and Lapointe that there would be no conscription for overseas service; and it felt that a Liberal government, without a union cabinet including Conservative anti-Quebec members, could prosecute the war with the least danger to Quebec's special preoccupations. Accordingly, 64 of the 65

Quebec members of the dominion parliament were elected by the Liberals. When the Rowell commission made its report favouring an increase in national as compared with provincial powers, King suspended consideration of it indefinitely. He accepted the Quebec idea that so long as no constraint was applied the French Canadians would furnish numerous volunteers for the armed forces, and in this policy he was strongly aided by the highly-respected Cardinal Villeneuve. The German capture of France shocked French Canada. King had no difficulty in enacting a national mobilization law, or in interning Mayor Camillien Houde of Montreal when the latter preached resistance to registration. Arcand and his acolytes had already been interned.

During 1940, the new Quebec legislature voted a number of important new laws, granting female suffrage in April, creating a ministry of social welfare in October and arranging the abolition of the archaic seigneurial land rents in November. In 1941 it took over for the province the large Beauharnois electric company, a step toward socialization which Duplessis' Union Nationale had not ventured.

Quebec and the War Effort.—Throughout 1941, the entente with the King government was maintained. Voluntary recruiting was as fruitful as in several of the English-speaking provinces, and Godbout announced that French Canada was thoroughly anti-totalitarian. A noteworthy physical disaster was the forest fire near Lake St. John which lasted a week and ravaged 2,000 sq.mi. of timber. A more significant misfortune was perhaps the death at the end of the year of minister of justice Lapointe at Ottawa, the greatest leader of the French Canadians since Laurier and a main bulwark of Premier King's policies. He was replaced by a distinguished Quebec jurist, Louis St. Laurent; and early in 1942 Quebec joined with the other provinces in ceding war income tax rights to the Dominion on a compensation basis. Many war industries were created in Quebec by the national government, with resultant full employment and prosperity.

By April 1942 Prime Minister King was forced by the military situation to hold a national plebiscite to secure release from his pledges against overseas conscription. Quebec felt that the pledges had been made to it rather than to the nation as a whole, and 72% of its votes was adverse. The country as a whole was favourable, and King announced that as yet he would not make use of this development. Some of his French Canadian leaders, notably P. J. Cardin, abandoned him in May when he asked parliament to modify the mobilization law; but when this was done they stated that they would not resist the new statute. The torpedoing of ships by the Germans in St. Lawrence waters had some influence; but Maxime Raymond, an eloquent national deputy of Montreal, organized a Bloc Populaire advocating complete autonomy for the province. At the end of the year King brought three new French Canadians into his cabinet.

Many French-Canadian military units showed great courage and loyalty in combat in Europe. During 1943 the Quebec legislature and the Quebec deputies at Ottawa both gave proof of devotion to King's war policies, although also opposing conscription; and the dominion laws providing a species of labour conscription were not resisted. The Roosevelt-Churchill conferences at Quebec were well received. A very large share of Canada's war supplies was produced in Quebec. The vast Shipshaw hydroelectric plants on the Saguenay commenced to operate, and the Sorel shipyards built large freight vessels. Nevertheless the forces of local Nationalism showed revival, and the Bloc Populaire scored a few by-election victories. The uneasiness

was increased by important Montreal strikes, adjustment of which proved painful.

National Union Government—Second Phase.—In the spring of 1944, Premier Godbout took over the Montreal Light, Heat & Power company, and arranged for a provincial hydroelectric commission, which should have enhanced the government's popularity with the voters. But the extinction of submarine activities and the Allied invasion of France created a feeling that the war danger was over; so that when a provincial election was held, on Aug. 8, the Duplessis party, stressing the conscription and provincial rights issues, was able to capture 48 seats of 91, and to assume control of the province. In December Mayor Houde was re-elected at Montreal.

Nevertheless, when Prime Minister King finally resorted to conscription in the autumn of 1944, the consequences in Quebec were less violent than might have been anticipated. Some Liberal leaders bolted or refused office, and there were a few popular disturbances, but as compared with the riots during World War I on the same issue, the reaction was very moderate. The mildness of King's strategy toward the province was even more apparent in 1945, when the national elections held in June gave him 60 of the 65 Quebec federal members and also marked the final exit of the Bloc Populaire. At the end of the year Duplessis had increased his hold on the provincial government through by-elections, due to his opposition to increased constitutional power for the central government; but he

made no headway as to dominion politics.

An outstanding development in 1946 was the enactment of a Quebec law for the exploitation of the extensive iron ore deposits of Ungava, said to be larger than those of the Mesabi range in Minnesota. The economic expansion continued in general with great vigour. At Ottawa the Quebec deputies showed resentment at proposals for the inclusion of British heraldry in the suggested new Canadian flag; but in other matters they supported the Liberal government of Premier King as being more sympathetic to their province than other governments were apt to be. (A group of young Liberals led at Ottawa by Rinfret and at Quebec by Arsenault gave promise of revitalizing their party.)

Queensland

The northeastern state of the Australian commonwealth, Queensland has an area of 670,500 sq.mi. and 3,236 statute mi. of coast line. The area of the state represents 22.5% of the Australian continent, and the occupied area 30% of the Australian total. Altogether less than 11% is unoccupied territory either for private production or for public reserves, and this is situated mainly in the north of Cape York peninsula. The area within the tropics is 360,000 sq.mi., this being 54% of the whole. Pop. (Census 1933) 965,234, (estimate 1946) 1,090,300. Chief towns: Brisbane (cap., pop. 1945, 384,500); Townsville (36,500); Rockhampton (34,000); Toowoomba (32,000); Ipswich (25,500).

An unrestricted adult franchise was adopted within the state for both the parliamentary and municipal institutions. The Queensland parliament, alone among state legislatures in Australia, continued to have only one house—the legislative assembly of 62 members. The

state cabinet consisted of ten ministers of the crown, forming the executive government and presided over by the governor, the king's representative.

During the decade 1937-46 the king's representative in the state was the Right Hon. Sir Leslie Wilson. A Labour government was returned to power at general elections held in 1938, 1941 and 1944, the consecutive premiers during this period were: W. Forgan Smith, who resigned in Sept. 1942; F. A. Cooper (Sept. 1942-March 1946); E. M. Hanlon (after March 1946).

The Queensland government, mindful of the disastrous effects upon local employment following the world slump in 1929-32, instituted in 1933 a program of public works and development which brought about a general improvement in employment figures throughout the state. An important extension of these plans took place in 1938, when the state parliament passed the State Development and Public Works Organization act designed further to encourage and stabilize employment by marshalling and co-ordinating the organization and control of public works and constructional utilities, and thus instituting a progressive system of public works and state development.

After the outbreak of war in 1939, the Queensland government, under the national safety regulations, applied measures to ensure that adequate supplies of essential commodities would be available throughout the state in the event of any interruption to transport either by sea or land, or through dislocation of trading facilities generally.

The state government gave all possible aid to the government of the Commonwealth of Australia in the prosecution of the war; particularly was this the case after the entry of Japan into the world conflict, when the vulnerable coast line of the state became the object of an attack by the Japanese sea and landing forces. At this critical time the Queensland government subordinated all other questions to the supreme purpose of co-operating with the commonwealth government in the war effort, by undertaking the construction of inland strategic roads, preparing and laying down sites for aerodromes, airfields storage depots and munition factories, improving dockyards and harbours, and by training munition workers, etc. Acts of parliament, regulations and orders were also promulgated for the welfare, order and public safety of the state and of its people.

Queensland, because of its geographical position, actu-

ally became the eastern bastion for the defense of the Australian continent as a whole. As a result, the state was called upon to play an all-important part in General Douglas MacArthur's plans for the defense of the commonwealth and the eventual attack upon the Japanese-held bases. The headquarters of the American forces were located in Brisbane in the early stages of the campaign in the southwestern Pacific.

Quezon, Manuel Luis

Quezon (1878–1944), Philippine statesman, was born Aug. 19, 1878, at Baler, Luzon, P.I., and studied law at Santo Tomas university in Manila. In his early 20s, he joined the Aguinaldo insurrection against the U.S., but later made his peace with the territorial authorities and became a provincial prosecutor in 1903. He was a member of the Philippine assembly, 1907–09, and resident commissioner to the U.S. congress, 1909–16. He was elected president of the Philippine senate in 1916, a post which he held until his election as president of the new commonwealth in Sept. 1935. Quezon was re-elected in 1941 by an overwhelming majority. After the Japanese invasion of the Philippines, Quezon reaffirmed his loyalty to the U.S. In May 1942 he established a provisional government for the commonwealth-in-exile in Washington, D.C. Although he was scheduled to step down from the presidency after his second term, as the commonwealth constitution limited the tenure of the president to eight years, the U.S. congress voted in 1943 to have him continue in office until civil government was restored to the islands. Quezon died at Saranac Lake, N.Y., Aug. 1, 1944.

Quisling, Vidkun Abraham

Quisling (1887–1945), Norwegian politician, was born July 18, 1887, at Fyrisdal, Norway, and was trained from his youth for a political career. After passing the Norwegian college examinations, 1911, he entered the army, was commissioned as a captain and promoted to a major of field artillery. He pursued a diplomatic career, as military attaché at Petrograd, 1918–19, and Helsinki, 1919–21. In May 1933, four months after Adolf Hitler became chancellor of Germany, Quisling formed the *Nasjonal Samling*, a Norwegian fascist party. He assisted the German invasion of Norway of April 1940 by using his military authority to delay mobilization and surrender certain key positions and by urging his countrymen not to resist the nazis. Hitler rewarded Quisling for his aid by making him, on Sept. 25, 1940, fuehrer of Norway. His task, the German occupation forces proclaimed, was to “reconstruct” his country in conformance with nazi principles. Quisling, who became prime minister in Feb. 1942, was never able to command the co-operation of Norwegian authorities; his treason was despised by most of his countrymen. Arrested after the Allied reoccupation of Norway in 1945, he was tried on charges of treason before an Oslo court in sessions that lasted from Aug. 20 through Sept. 10, during which the puppet leader denied the treason charges and contended he was the “saviour” of Norway. The seven-man trial court found Quisling guilty on Sept. 10, 1945, on numer-

ous counts, including murder, treason and theft, and sentenced him to die before a firing squad. The man whose surname had become a synonym for traitor, was executed Oct. 24 and his body was cremated immediately thereafter.

Radar

Though it was as early as 1886 that Heinrich Hertz discovered that radio waves were reflected from solid objects, modern methods for the use of such reflections in detection of ships and aircraft originated with experiments to measure the height of the ionosphere—the layer of ionized gases in the upper atmosphere which reflects radio waves of long and medium length downward and permits them to travel around the earth.

In the summer of 1925, Dr. Gregory Breit and Dr. Merle A. Tuve, of the Carnegie Institution of Washington, began to use radio pulses for such measurements. Each pulse lasted a thousandth of a sec., during which it could travel 186 mi. It was shown by a hump in a line of light on the face of a cathode ray oscillograph. A fraction of a sec. later the echo returned and was similarly indicated. With speed of propagation being known, the distance to the ionosphere was determined. The advantage of the pulse method over a continuous wave was that the faint echo, was not overpowered by the radiation from the transmitter. A continuation of these experiments in 1938 used a pulse less than 0.004 sec. in length, repeated 300 times per sec. so that the silent period was about eight times the length of the pulse.

In 1922 Dr. A. Hoyt Taylor and Leo C. Young, at the Naval Research laboratory, had noticed a distortion in reception of radio signals caused by reflections from a steamer on the Potomac. This led to a suggestion to the navy department that “destroyers located on a line a number of miles apart could be immediately aware of the passage of an enemy vessel between any two destroyers of the line, irrespective of fog, darkness or smoke-screen.”

During experiments with radio direction finding equipment in the summer of 1930, Taylor and Young observed similar effects with an aeroplane, and a project to apply radio methods to the detection of ships and aircraft was started at the laboratory. This method functioned through the interference of the direct with the reflected wave, when both arrived at the receiver. It was necessary that the transmitter and receiver be some distance apart, thus limiting its application, particularly on shipboard. It seemed, however, suitable for land installations and the army was informed of the work in 1932.

Young had taken part in the 1925 ionosphere experiments, and late in 1933 he proposed that the same method might be a solution to the problem of placing receiver and transmitter on the same ship. During the next few years, with the aid of an appropriation of \$100,000 by congress in 1935, work continued at the laboratory. Circuits to generate pulses of the proper length and shape, sensitive receivers, methods of displaying the data on cathode ray tubes and a duplexer, which permitted the same antenna to be used both for receiver and transmitter, were developed.

The resultant equipment was demonstrated at the laboratory in June 1936, to representatives of the navy's bureau of engineering, and its success led to another demonstration on Feb. 17, 1937, to Charles Edison, then asst. secy. of the navy, and Adm. Leahy, chief of naval operations. During 1936 the army signal corps laboratories had designed and built their first equipment using pulses and had detected commercial aeroplanes flying over New Jersey. In May 1937 a demonstration was given to the secretary of war and members of congress at Fort Monmouth. In addition to detection of the test bombers, it gave information about direction, elevation and range, so that searchlights could be aimed accurately at the planes.

The first shipboard system was installed by the Naval Research laboratory in Dec. 1938 on the U.S.S. "New York." Exhaustive tests were made during battle manoeuvres early in 1939. Both the commanding officer of the "New York" and the commander of the battleship division were so enthusiastic about the results that full support to continuation of the program was forthcoming. In Oct. 1938 the first contract to a commercial firm was awarded when six additional sets, duplicates of the "New York" installation, were ordered from a large radio manufacturer.

Meanwhile, the British had developed their own system, very similar to that of the U.S. navy. This, too, had resulted from publication of the early Breit-Tuве experiments. At the National Physical laboratory, by 1935, a similar technique was in use for measuring the ionosphere and Robert Watson-Watt, head of the radio department conceived the idea that aeroplanes might be detected by similar methods. An experiment with radiation from the high-power station at Daventry gave encouragement, and in Dec., 1935 it was decided to establish a chain of five stations on the east coast of England, the first operational radar system in the world. In Aug. 1937, 15 additional stations, covering the whole east and southeast coasts, were authorized.

At the same time, also springing from the ionosphere measurements, experiments were being carried on in Germany. As in all countries which were developing such devices, they were conducted under a heavy cloak of secrecy.

By 1940, as U.S. defense activities were accelerated, work in aircraft detection shared this expansion. Co-operation among various arms of the service in their developments, and also among scientists in the United States and Great Britain, was effected. The U.S. navy had coined the word "radar" (for "radio detection and ranging") to designate the work, and this soon replaced other terms, such as "radiolocation" and RDF (radio direction finding), used in Britain, and RPF (radio position finding) which had been used by the army signal corps.

Another important step was made in June 1940 when the National Defense Research committee (NDRC) was set up by executive order, with Dr. Vannevar Bush at the head. Long-range research problems in radar were turned over to this group, which worked through university and industrial laboratories. By July 1940 a Microwave committee was formed, under Dr. Alfred L. Loomis as chairman, to work on the problem. In Sept. 1940 a British Technical mission, headed by Sir Henry Tizard, arrived in the United States, and mutual disclosures were made of U.S. and British work. The Americans were shown the British-developed cavity magnetron, an electronic tube for the production of short wave radio pulses at high power, and

soon equivalents were made in the United States.

A conference on Oct. 12, 1940, between members of the British mission and the Microwave committee started what was to be one of the most important radar accomplishments in America. Up to that time radar had used waves of the order of length of a few ft. but now it was decided to undertake intensive developments in the microwave region—with waves only a few in. in length—particularly in respect to a system for aiming anti-aircraft guns, and another for aircraft interception.

As a result there was established at the Massachusetts Institute of Technology a new Radiation laboratory, staffed by physicists from many universities, and headed by Dr. Lee A. DuBridge, of the University of Rochester. This was administered by the institute under a contract from the NDRC. The laboratory opened its doors in Nov. 1940 and soon became the chief centre of long-range radar development. Early in 1941 its personnel had grown to nearly 4,000. By the end of June the first contract had been awarded for commercial production of microwave radar equipment, but it was not until 1943 that microwave sets of many types were being turned out on a large scale and were beginning to have an important operational role. By the end of the war these techniques were employed in most of the Allied radar equipment and were largely responsible for its superiority over axis radar.

In the meantime the U.S. army and navy, in their own laboratories, were concentrating on the urgent problem of getting radar into use on land and sea. Sets using medium length waves were installed on many ships and at a number of land stations. One of these sets, at Pearl Harbor, actually detected the approach of the Japanese planes on Dec. 7, 1941, at a distance of 135 mi., and it was no fault of the equipment that its warning went unheeded.

When attacks on England by the luftwaffe began in Aug. 1940 the British chain of radar stations clearly demonstrated its value. The R.A.F., critically short of fighter planes and pilots, was unable to maintain constant patrols around the island to combat the Germans. By radar, however, the German raids could be detected well in advance and the few to whom so many owed so much could be used with the most effect. Nazi losses increased, so night attacks replaced daytime raids.

With daytime attacks, the defending fighters were brought into the general vicinity of German planes and each pilot then used his own judgment for a choice of targets. At night, however, a radar operator on the ground would follow a specific nazi plane and give radio instructions to the fighter which he controlled until he was a few mi. behind the target. Then, by a radar on the plane itself, the pilot would be guided close to his quarry and the attack was completed. Sometimes one radar controller, in a single night, would be responsible for the destruction of as many as six German planes.

* * *

AN IMPORTANT ADJUNCT to radar was IFF (identification, friend or foe). This enabled the radar operator to tell, by means of a return signal from a special transmitter on the plane, whether the approaching plane was a friend or an enemy. Later it was extensively developed—for use on ships as well as aeroplanes.

During World War I, sound locators were used for locating approaching aircraft, which would then be picked up by optical range finders and tracking telescopes. At night the plane would have to be picked up on the beam of a searchlight before the optical equipment could be used and anti-aircraft guns aimed. As the approach of

World War II brought faster and faster planes this method became quite inadequate. Radar took the place of the sound locators, but still the data obtained had to be fed to the computers controlling the guns. By 1943, however, as a result of extensive research and industrial co-operation, the army had developed a microwave radar which could aim the guns automatically. This was used in conjunction with a new type of electronic computing device, which made the necessary allowances for such factors as the movement of the plane while the projectile was in flight. It controlled the motors moving the guns and also set the fuse on the shell to explode at the right time. The over-all result was anti-aircraft artillery of a new order of accuracy.

This combination proved most effective against V-1, the "buzz bomb," which the Germans began to send over England in 1944. Some were caught by the balloon barrage. Others were shot down by fighter planes, though only the fastest could catch them. Radar showed the presence of V-1s and also permitted a plot of their paths back to the launching sites, which could then be destroyed by Allied bombing. But finally anti-aircraft artillery, guided by radar through the electronic gun director, shot down the bulk of the buzz bombs. The same equipment was also used effectively both against V-1 and manned aircraft following the Normandy invasion, though by that time the luftwaffe was considerably weakened.

In the Pacific similar equipment was effectively used against Japanese planes and naval radar also demonstrated its effectiveness. In one early case of night action in the Solomons, a U.S. battleship was able to locate and sink a

U.S. carrier with radar antennae visible against the sky. Radar fire control directed the fire of the 5-inch anti-aircraft batteries in the foreground, and fighter director radar guided the carrier's planes to enemy targets

Japanese ship eight mi. away at night, although the ship was not visible until actually on fire.

Various kinds of antennae were used for radar. Early medium-wave sets used an array of elements arranged on what looked like a large bed spring, but this gave rather a wide beam. As microwaves came into use the antenna was placed at the focus of a parabolic metal reflector, which had the same function as the silvered glass mirror of a searchlight. The fineness of the beam depended on the size of the reflector relative to the wavelength. Longer waves could be focussed in the same way but the reflector would have had to be unduly large. With microwaves it was a simpler matter to get a narrow beam. This increased the precision of the apparatus, and also concentrated the energy, giving longer range. In most sets, the same antenna served both as transmitter and receiver. A device called a T-R (transmit-receive) box disconnected the transmitter when the echo returned, and fed the signal into the receiver.

To present the data obtained, cathode ray oscillograph tubes were generally employed. These were similar to the tubes used in a television receiver. The tube was pear-shaped; in the narrow part was a source of electrons which were fired at the wide end, coated on the inside with a fluorescent material which glowed where electrons strike.

The A-type of presentation was one of the earliest. For each pulse sent out, lasting a few millionths of a sec., the electron beam traced a horizontal line. At the left-hand end, a vertical hump appeared, representing the transmitted signal. A returning echo produced a second hump, or "pip," its distance from the first indicating the range of the target causing the echo. Another, the B-type presentation, showed the azimuth of the plane by the horizontal position of a spot, while its height on the face of the tube indicated range.

One of the most useful of all, however, was the PPI (plan position indicator) which, in effect, drew a map of the region around the radar—perhaps to a distance of 100 mi. or more—and showed in their proper position all targets within range, as well as topographical features.

The antenna on the radar would sweep around the horizon, every few secs. A fine radial line of light, traced by the electron beam, would sweep around the face of the tube in synchronism. Several hundred times a sec. the pulse would go out, and when an echo returned the radial line would brighten at a distance from the centre proportional to the actual distance of the reflecting plane or ship. The phosphor with which the tube was coated was phosphorescent so that even though the fainter glow from the line itself quickly faded, that from the target would continue until the line swept past again, when it would be renewed. Thus, as a plane came into range, the spot would be seen moving across the face of the PPI scope in a way that corresponded with the actual movement of the aircraft in space. In many sets, the range was adjustable. At first the PPI might be used to detect planes at 100 mi. or more, then as the targets approached, a turn of a switch would shift to a shorter range, which would show the region around the set on a larger scale.

This type of presentation was used on land sets, marine installations, and from the air. In addition, for airborne sets, there was another type which in effect gave the flier a window through which he could look straight ahead, even in total darkness or through clouds, and see other planes in that region. The radar beam would sweep through a rectangular area forward, and the scope would show the re-

flections, with positions corresponding to their actual places. An ingenious addition to such sets was the "winged pip". That is, the spot of light showing the presence of a reflecting object was made, by electronic circuits in the receiving set, to grow "wings," a little horizontal appendage on each side. The length of these wings would increase as the range decreased, thus giving a quick means of determining distance. When the wings had grown to the correct size, as indicated by vertical lines on the face of the scope, and when it was exactly centred, the other plane would be at correct range; the guns were then properly aimed, and fired with the virtual certainty of a hit.

* * *

SOME of the most remarkable aerial achievements of radar were with radar bombing, also known as BTO ("bombing through overcast"). After British experiments with a modification of equipment which had been intended to enable planes to search for ships at sea below them, and which showed possibilities of the method, Radiation laboratory scientists developed a set using shorter waves, and hence giving greater precision.

The beam from an antenna in a parabolic reflector would scan in a conical region centred directly below and the presentation was on a PPI scope. In general, land areas reflected radar pulses better than water and building and other structures produced characteristic effects. Thus, the radar scope showed a virtual map on which coast lines, rivers, bridges and other features could be identified with ample accuracy to aim bombs.

After the U.S. army air forces requested such sets in June 1943 Radiation laboratory undertook, with army and navy help, to build 20 outfits on a "crash" basis. These were completed and received their first operational test on Nov. 3. Nine "pathfinder" planes of the 8th bomber command, each equipped with BTO took off on a "practice" run over Germany. Each led a combat wing of 60 planes. They went over Wilhelmshaven, a target which had been missed on eight previous raids, guided only by visual aiming methods. Even though the target was completely hidden by clouds, the bombs were accurately dropped by radar aiming, a point confirmed by later reconnaissance photographs.

During the rest of Nov. 1943 the 8th air force made more raids than ever before in a single month and in December dropped the greatest tonnage of bombs (24,000) ever dropped in a similar period—a marked contrast to the previous December, during which it had been grounded. In this whole period of two months, there were only four raids during which weather over the target permitted visual aiming; all the rest were radar guided, the bombing formation flying behind a few Pathfinder planes.

Though radar permitted bombing under weather conditions which formerly would have prevented any bombing at all, it was not as accurate as visual aiming. This was finally recognized in the adoption of techniques, which permitted the visual bombardier to aim if he could but held the radar operator ready to take over if necessary. The method was described in *Radar: A Report on Science at War* (1945) as follows:

"A technique for coordinating the work of the B.T.O. operator and bombardier was worked out so that every mission, no matter how the bombs are aimed, is run in the same way. Radar is always used for every run to navigate to the initial point and to get squared away for the bomb run. The radar operator goes on as if he were going to do

the whole job, and the optical bombardier keeps his sight lined up according to the radar set-sighting. This means that, if the radar is right, the telescope of the Norden is always kept pointed at the aiming point, which is down there below the clouds. The slightest break in the under-cast which permits the bombardier to see enables him to take over the run and complete it optically. This system joins the best features of radar and visual bombing, and makes the bombardier and radar operator a team instead of competitors."

By the end of the war, radar sets in a wide variety of sizes and types were being made and used. Some of the largest and most elaborate naval sets weighed many tons and gave range, altitude and other data about planes detected. Smaller, more compact sets were built which could be floated ashore in an invasion and quickly set up on shore. Others were mounted in trailer trucks, which could speedily be moved around, while still others were permanently mounted in harbour installations. A simple and small airborne set was installed in the tails of fighter planes to give warning by means of a bell or flashing light of any plane approaching from the blind region directly behind. And closely related to radar were sets used as proximity fuses in anti-aircraft and artillery projectiles. These did not need to hit to explode. The fuse contained a miniature radio transmitter which sent out a signal. When a reflection came back from a certain distance (or from the ground) the shell exploded.

Not strictly radar but closely related to it, were the various kinds of radio beacons. These worked by methods similar to the IFF equipment on aeroplanes. That is, the radar pulse from an airborne transmitter would trigger off a beacon transmitter on the ground and the return signal produce a characteristic indication in the radar scope. This would be coded so that the aviator could identify the responding beacon.

Then there was Loran (for "long range navigation") which was set up around the world and proved a valuable peacetime guide to navigation, both air and marine. This was developed in the Radiation laboratory, independently of a British system using the same general principles. The latter, however, used shorter waves and was not applicable over very great distances. Loran, however, used wavelengths comparable to those for transoceanic broadcasting, and operated over distances of 1,000 mi. or even more.

Loran stations operated in pairs—a master and a slave. First the master sent out a pulse travelling in all directions, to a ship at sea and also to the associated slave. Here a transmitter was automatically triggered and a second pulse was emitted, which also went to the ship. On the vessel there was a special receiver which picked up both pulses and showed on a cathode ray oscillograph screen the difference in time of arrival, automatically compensating for the delay while the master signal was reaching the slave and triggering it off.

If the two signals, after this allowance, arrived simultaneously it showed that the ship, or plane, was on a straight line half way between the two transmitters and at right angles to the line joining them. If one signal arrived at two-thirds of the time required for the other, then the ship was some place along a curved line—a hyperbola—where this ratio of distance was the same. Thus, one might draw a family of such curves on a map of the area around the

→
"Contact" with the moon was first established on Jan. 10, 1946, when a radar signal beamed at the moon from U.S. signal corps laboratories at Belmar, N.J., echoed back in 2.5 seconds. Similar methods were expected to be used for charting the topography of distant planets

stations and, by loran observations, the ship's navigator could accurately place his craft on one of them.

This would not show where he was, since part of the proper curve might be on land. However, if there were another pair of stations nearby, their master and slave pulse could also be received and the ship would then be placed on a curve drawn with respect to them. The intersection of the two curves, then, was the position of the ship and this could be given with accuracy as great as from observations of celestial bodies. Kept highly secret during the war, loran charts prepared by the navy were made available for navigators after the war's end, and the equipment was being made commercially, so that these methods—often referred to as "hyperbolic navigation"—might become a common procedure for commercial ships and aircraft.

Radar Countermeasures.—The introduction of any new weapon always brings up the matter of countermeasures, and quite early in World War II some slight preliminary consideration had been given to methods by which radar, if used by the enemy, could be countered. But this research did not have very high priority. Then, early in 1941, the British had the German battle cruisers "Gneisenau" and "Scharnhorst" safely (as they supposed) bottled up in Brest harbour.

British radar along the channel coast and on ships could presumably detect an attempted escape even under cover of fog.

But on Feb. 11, aided by such protection, the ships did escape by "jamming" the British radar.

This feat emphasized the importance of radar countermeasures, referred to as RCM, and an active program began. At first this took place in Great Britain, because that country was actually at war, but even in the U.S. studies were begun. After Pearl Harbor these activities were accelerated. A group was set up at the Radiation laboratory early in 1942 and charged with responsibility for RCM. A little later, however, it seemed that it could best work as an independent establishment, and it was organized at Harvard university as the Radio Research laboratory, working under the auspices of the NDRC, and with Dr. Frederick E. Terman of Stanford university as director. At first it was under the control of the NDRC division charged with responsibility for radar and the Radiation laboratory. At the end of 1942 a separate part of NDRC, later called Div. 15, was formed. Dr. C. G. Suits, later director of the General Electric Research laboratory, was appointed chief.

The Radio Research laboratory, which was assigned the development of systems, was the largest single group working on the U.S. radio countermeasures program, but important contributions, particularly in the development of new types of electronic tubes, were made by the armed services themselves and by other laboratories, both university and industrial. Under Div. 15, many kinds of axis electronic weapons were countered, but efforts against radar were the most important. About two-thirds of the total of \$31,000,000 expended by the division went into this phase of the work.

Radar countermeasures, more than most wartime scientific developments, were of necessity closely tied in with actual military operations. Just as soon as the axis knew that its radar was being countered, it would try to overcome these measures. Then additional countermeasures were necessary, so there was a constant race between laboratory and axis evasions. This was accomplished by a close co-ordination between the U.S. armed services and

Div. 15. In 1943 a laboratory was set up in England, which was much closer to the scene of operation. Located at Great Malvern, it was close to the Telecommunications Research Establishment, centre of British activities along similar lines.

A still further step was that of counter-countermeasures. Since the Allies were using countermeasures against the axis radar, it could be presumed that the axis would try the same tactics. Therefore, in the design of radar sets, efforts were made to incorporate anti-jamming features that would make them more difficult to jam successfully. This was accomplished by close co-operation between Div. 15 and the Radiation laboratory.

There were four weaknesses of radar which could be exploited in countermeasures. The emitted pulse, even though focussed into a beam, was weakened with distance. The echo from a plane or ship was not focussed but spread in all directions, and so, already much weaker than the original signal, it rapidly suffered further attenuation. Thus, the echo returning to the radar receiver was far more feeble than the pulse sent out. In order to make the echo strong enough to be heard easily the transmitted pulse had to be of tremendous strength and this could be heard by any receiver tuned to the correct frequency. Consequently, a radar set continually advertised itself and could be heard by a "search receiver" at a distance well beyond that at which it could detect an object.

When an operating radar was found, a radio direction finder could be used to determine its direction. If this was done from two separated points, the lines of bearing could be drawn on a map and the position of the radar, at the intersection of these lines, accurately located.

Again, the weakness of the echo returning meant that a louder signal would cover it. In the same way a man listening for an echo of a shout from a cliff might be prevented from hearing it by another man, shouting louder than the echo. To jam a radar echo a transmitted signal did not need to compete in power with the original pulse—it merely had to be stronger than the returning echo. A relatively small box of electronic equipment, carried in a plane, might be able to put a large radar set, weighing many tons, out of use.

The fourth weakness of radar was its inability to distinguish the exact nature of a small target. Radar waves could be reflected by thin sheets of metal foil as well as by aeroplanes, and the indications on the radar scope were similar.

Early in the war both sides seem to have conceived the idea of dropping sheets of foil to give false reflections on the other's radar, but each side was afraid to use it because the other would then learn the secret. Later it was found that thin metallic strips of correct length would resonate to the frequency for which they were cut and thus a relatively small number of strips, dropped from a plane and allowed to scatter in a cloud, could make as much of an echo as a large aeroplane.

These strips were known by the code name of "window," which was first used by the R.A.F. with great success in a raid on Hamburg in July 1943. The losses were only a fraction of those sustained on previous raids. The first window was paper backed but later at the Radio Research laboratory a machine for cutting it from rolls of aluminum foil was devised, which gave it the necessary stiffness by a crease down the middle of the strip. With material so made a bundle weighing less than two oz. scattered through the air would give a radar signal equivalent to that from a large bomber.

The method was to drop a number of packets out of the

leading plane in a formation, either by hand or with an automatic dispensing machine. Hundreds of planes might fly along in the trail produced, and the radar would no longer be able to track them. The cloud of foil acted as an electronic smoke screen which hid them from radar just as a real smoke screen would conceal them from visual detection. During the war a total of 10,000,000 pounds of window were dropped over Europe by British-based U.S. bombers.

* * *

ANOTHER variety of "confusion reflector," known as "rope," consisted of long ribbons of foil and was used largely in the Pacific area. These were attached to small parachutes to retard their fall. Rope was effective over a wider range of radar frequencies than window, which had to be cut for certain particular frequencies, though sometimes packages of assorted sizes were used, so that several different radars might be countered. Since a cloud of window would settle slowly through the air its range, as indicated on the radar screen, would not change; this would enable the operator to distinguish it from the rapidly moving planes. As soon as they would fly out of a cloud of window, they would no longer be protected.

Though it lacked the simplicity of window, electronic jamming was widely used and was even more effective. This consisted in broadcasting a continual program of noise on the frequencies used by the enemy radar, so that it drowned out the indication of the faint echo. On the radar screen, with A-type presentation, this appeared as many fine blades of grass which might completely hide the vertical pips indicating a plane or ship. On the PPI, it made a general brightening of certain areas, covering the wanted reflections in those regions.

One type of electronic jammer, developed at the Radio Research laboratory and known as "carpet," was designed to be used against the German Würzburg radars used to aim anti-aircraft guns. After development of radar bombing methods, enabling raids to be made through clouds which hid the bombers from the ground, the axis was forced to rely on radar exclusively to detect and bring down the planes. In Oct. 1943 carpet was first used in a raid on Bremen. The planes equipped suffered less than half the losses of those not so provided. By the end of the war in Europe, every heavy bomber of the U.S. strategic air forces was provided with at least two radar jamming transmitters. The use of such equipment along with window largely neutralized German radar.

How effectively these measures operated was not appreciated until after V-E day, when interrogation of German personnel, from generals down to actual radar operators, indicated that after countermeasures came into large-scale operations the effectiveness of the radar-controlled anti-aircraft was reduced to 25% of normal.

The frequencies chosen by the Germans for the Würzburg system happened to be about those most susceptible to jamming methods. On the Allied side, the trend was continually to higher and higher frequencies, into the microwave region with waves only a few in. in length. These were harder to jam, and axis countermeasures never offered any serious threat to Allied radar. As early as Jan. 1943 the Germans had recovered a working Allied microwave radar from a crashed bomber. However, they had such a large investment, est. at \$1,000,000,000, in their Würzburg equipment that they bent their major efforts to salvaging it, rather than abandoning it in favour of a new and less susceptible system.

At first the Germans tried to keep their people from

knowing the effects of Allied countermeasures but later the situation became so desperate that the luftwaffe announced a public contest, with prizes amounting to 700,000 RM (to be free of all taxes) for the best solution to the window problem. At least half of their radio experts were engaged in these efforts. Some 13 anti-jamming devices were devised and placed in service, and at least 19 more were under development when the war ended.

One class of device was based on a shift of frequency of their radars to avoid electronic jamming; another was to distinguish between moving and stationary targets, and thus to overcome window. In most cases, it was impracticable to employ both at once. Use of devices against electronic jamming made their radar vulnerable to window, while the anti-window devices failed to protect against the carpets.

"Since all evidence has shown that the effectiveness of German radar-controlled antiaircraft fire against blind strategic missions during the period from Sept. 1944 to May 7, 1945, was approximately 25 per cent of normal," states *Electronics Warfare*, the report on radar countermeasures issued by the Joint Board on Scientific Information Policy, "it can be said that radar countermeasures undoubtedly saved the United States forces in England roughly 450 planes and 4,500 casualties. The cash value of 450 four-engined aircraft alone is approximately \$150,000,000, or about twice the cost of the entire flak countermeasures program. Roughly, the same considerations apply to our strategic Air Force in Italy, whose size was fully half that of its British-based counterpart."

In 1942 a special problem arose in connection with the radar, known as lichtenstein, used by the German night fighters against British bombers. Jammers could not be used on the British planes themselves, for then direction finders on the fighters would locate them as easily as radar could. Accordingly it was decided to install in England a large jamming transmitter 1,000 times more powerful than ever used before in the frequencies involved. This was called "tuba" because of the huge parabolic antenna. With it a jamming beam could be directed over the continent. In this beam British bombers could fly safely back to their bases, knowing that the lichtenstein-equipped fighters that tried to find them would be blinded.

Tuba was built at the Radio Research laboratory, on the basis of a new electronic tube called the resnatron. Originally conceived about 1938 by Dr. David H. Sloan and Dr. L. C. Marshall, at the University of California, it was perfected by Dr. Marshall in the Westinghouse Research laboratories. Its power was of the same order as that of the most powerful U.S. broadcasting stations (50,000 watts), but its frequency was 500 times as high. In June 1944, less than a year and a half after work began, the first installation, carried in seven army trucks, was in operation in England. Later the British ordered two more outfits.

Countermeasures were very effective in the Normandy invasion. Several days before D-day a concentrated attack was made by air against German radar installations all along the channel coast, with bombs, rockets and machine guns. Even so, when the invasion began, a few radars were still operating, and these would have been enough to reveal what was going on. The night before D-day air-borne jammers carried in planes cruising along the English coast jammed the German long-range radars so that they could not detect air squadrons forming over England and approaching the continent.

On the morning of D-day a few Allied bombers flew in

over the Dover-Calais area, using window and electronic jamming to simulate a large raid headed for Germany. This drew a number of German planes into an unsuccessful search to the east of the main invasion forces. There were also naval diversionary forces which approached the French coast just south of Calais, and another south of Dieppe. These ships had special reflectors to increase their radar reflection and make them look much larger. Moreover, enormous quantities of window dropped over them by low-flying aircraft made them seem to radar like one huge convoy. Such tactics caused considerable confusion to the Germans and enabled air-borne troops to land on the Cherbourg peninsula almost without opposition. Similar methods were used later in the invasion of southern France.

In the Pacific, conditions were entirely different, and countermeasures had to be used in quite another manner. There were many invasions, in widely scattered places, and operations were largely naval. Radar countermeasures, therefore, were made a fleet-wide activity, and each ship was given RCM equipment which made it self-protecting. It was operated under direction of the radar officers, who became electronics officers.

For the ship transmitters, the continuous wave magnetron became one of the vital tubes. The original magnetron, in which the flow of electrons was controlled by a magnetic field, had been invented by Dr. Albert W. Hull, of the General Electric Research laboratory, while work in England had adapted it for radar work, where pulse transmission was needed. For RCM, however, transmission had to be continuous, and this imposed severe requirements on the tube. However, in the same laboratory where the magnetron was born it was adapted by Dr. Hull and his associates to this new requirement, and at the end of the war there was a complete line of CW magnetrons covering a wide range of frequencies.

Particularly important in the fleet operations, especially with radar-guided suicide planes, was search and direction finding equipment. This was set to the frequencies used by the Japanese, and worked 24 hr. a day while there was danger of attack. Listening through a pair of headphones, and watching a scope similar to that of a radar set, the operator would sweep back and forth, tuning different frequencies. The sound of a Japanese radar was characteristic. At first it wavered, showing that the enemy was still searching for his target. But then, if it grew strong and steady, it showed he had found it and was coming in for a suicide attack. Then a U.S. night fighter could be sent out to intercept the Jap, since his direction was determined. Since the shipborne radar had much longer range than those on the Japanese planes, he could frequently be detected before he was able to locate his target. If the Japanese plane was not intercepted, and came in for attack, jamming signals could put the pilot's radar out of use, and often he would then give up and return home.

In the B-29 Superforts, planned for use over Japan, space was provided, along with adequate power, for installation of jamming transmitters and search receivers. On some of the first raids in which these planes were used it was found that Japanese anti-aircraft fire through clouds and the night searchlight control was unpleasantly accurate, which indicated the use of radar control and this was confirmed by the search receivers. By the end of the war, every B-29 was equipped with at least one jammer and some had two. They also used large quantities of rope, sometimes as much as 600 lb. being carried in one plane

Radar plotting board on a U.S. carrier during a strike against the Japanese in 1945

on a single mission.

During the day, since these huge bombers flew in close formation, a jammer in each plane was satisfactory, since one could protect the others. At night, however, the B-29s flew about a mi. apart, and if each plane were provided with enough jamming equipment to protect itself, and its immediate neighbours, from all the Japanese radars that might be encountered, the useful bomb load was materially curtailed. As an alternative, jamming gear was mainly concentrated in a few special B-29s, called Porcupines because of the numerous spinelike antenna that projected from them in all directions. Sometimes they would carry as many as 18 jammers in addition to necessary receivers.

As the Japanese radars were of low frequency, with broad beams that covered a wide area, Porcupines did not need to be very close to the other planes to protect them. Thus, they would fly over the target at a greater altitude than the bombing planes, and were safely above flak. Such tactics proved most effective.

Postwar Applications.—For peacetime use, radar had many possibilities. Several electronic manufacturers began to produce a simplified marine radar, with PPI screen, for use on merchant ships. This enabled the navigator, even in fog, to see buoys, nearby ships and features of the coast. A set having similar properties would be equally useful in the air while a very simplified model, such as the tail-warning set used on fighter planes, might be adapted to warn of approach to mountains or tall buildings. Sets on the shore, overlooking harbours, should be useful in detecting approaching ships, under conditions of low visibility, and airports might be similarly equipped.

Equipment for navigation with the use of loran was made available for ships, as already noted, and loran charts were released from secrecy.

For land transport, the application of radar would be considerably more difficult. It could hardly be applied to a railroad, e.g., because reflections from buildings and other structures along the way would produce so much "ground clutter" that the reflection from another train could hardly be identified. Moreover, if two trains were

at opposite ends of a curve, with obstructions in the straight line between them, the signal might be screened. Perhaps, however, an adaptation of IFF, or radar-beacons, might be adapted for such use. One train would be equipped with a radar-like transmitter and receiver, but it would pick up the impulse from another transmitter on the other train, which would be triggered from the first. This might prove useful in preventing collisions.

Possible astronomical uses of radar were suggested in Jan. 1946 when it was announced that the army signal corps had succeeded in detecting a radar echo from the moon, at a distance of about 238,000 mi. This was done with a modified army radar set and a specially built receiver of extreme sensitivity to detect the greatly attenuated echo, which arrived after an interval of about 2.5 secs. These results were mainly qualitative, as measurement of distance was only to the nearest 1,000 mi. However, if the method could be refined sufficiently to give instantaneous determinations of the moon's distance to within a mi. or less it would be a useful aid to astronomers. With the double attenuation of the signal, both on the journey out and on the return, a far higher order of power and sensitivity would be required to secure an echo from even the nearest planet, Venus, which approaches to within approximately 26,000,000 mi.

Radar countermeasures, as such, probably would have slight peacetime usefulness. However, the techniques developed in designing and building RCM equipment showed considerable promise. The pulse transmission of radar had little connection with ordinary radio, such as broadcasting and television. RCM, on the other hand, used a steady signal. Such tubes as the CW magnetron and the resnatron made it possible to produce continuous waves of high power and of far higher frequencies than those used before the war. These could be used for television and FM broadcasting. By opening up a new range of frequencies in the microwave region for exploitation, they might thus make room not only for more broadcasting and television stations, but also for numerous other radio services. In addition, high frequencies at high power might have important industrial applications, e.g., in methods of electronic heating of materials. (See also PHYSICS; STANDARDS, NATIONAL BUREAU OF.)

Radio

Radio achieved a new and far more authoritative role in world affairs during the decade 1937-46. For the first time, it served as an acknowledged instrument of war. In war and peace, its voice was employed to divert, inform, persuade, or command its listeners, and sometimes to combine these functions, depending upon the nations or persons in charge of programming.

Programming

The most universal trend in specific types of radio programming was the consistent increase in volume of news reports and commentaries, a result first of the spreading international tension and later of World War II itself. In most nations of the world, stations devoted two

and in many cases three and four times as many radio hours to news in 1945 and 1946 as they did in 1937.

Among the major networks of the United States, the Cooperative Analysis of Broadcasting (C.A.B.) reported that the amount of time sold for newscasts, commentaries and talks during the evening hours increased from 9.7% of all commercial time at the end of 1937 to 17.9% during the winter of 1944-45, exclusive of network sustaining newscasts and the time which affiliated and independent stations spent on local news and local summaries of world news. In a survey of stations, *Broadcasting*, the weekly trade journal of radio, found them devoting 15% to 20% of their air time to news at the end of World War II, compared with about 5% in prewar days. Nor was there any perceptible falling off of news time following the end of World War II, as networks and stations sought to acquaint listeners with developments in such fields as peace planning, reconversion, atomic energy and politics. Stations made up in additional local news any postwar reduction in time spent reporting world events.

No comparative data were compiled to show programming trends of the decade according to nations. Roughly, trends in United States radio, where the audiences, as well as the expenditures on programs to inform and entertain them, far exceeded those of any other nation, may be said to have been typical of trends elsewhere. This was particularly true of radio in nations which, like the United States, observed the principle of "free radio" as against government-controlled radio.

Variety programs in 1946 as in 1937 were the most popular type. Quiz shows and other broadcasts with audience participation showed a large "net" gain, although they were accorded somewhat less time in 1945 than in 1941, one of their peak years. Daytime serials, or "soap operas," lost neither in popularity nor in number. On the other hand, the amount of network time devoted to programs of popular music declined steadily, although they still claimed 10% of all network evening commercial time in 1945. Programs devoted solely to classical and semiclassical music lost even more ground, but were on the upswing in 1945 as compared with 1941.

Statistically, programming trends of the decade were reflected in the following compilation of C.A.B. measurements of U.S. network evening commercial time allocations:

Type of Program	Percentage of Total Time		
	1937-38	1941-42	1944-45
Variety	29.8	22.6	27.8
Comedy drama	8.0	10.9	6.7
Straight drama	10.7	12.7	8.9
Melodrama	6.6	7.8	7.8
Audience participation	7.7	14.5	10.0
Classical, semiclassical music	10.0	2.8	4.9
Popular music	14.3	12.6	10.0
Band music	0.5
Commentators, news, talks	9.7	10.9	17.9
Popular singers	2.6
Familiar music	5.2	4.0
Children's programs	1.7
Hymns	0.3

The period covered in each column is from October of the first year to the following April. The figures were prepared by C.A.B. for *Broadcasting's Yearbook*. Each program type was allotted the number of hours which all programs in that type represented. Fifteen-minute programs broadcast five times a week were counted as one and one-quarter hours a week, etc.

During the daytime, the greatest emphasis by all odds was on serial drama (47.3% of all network daytime commercial broadcasts during the winter and spring of 1944-45); for that reason daytime programs need not be broken into categories.

Several shifts in position occurred among the "Top Ten" individual programs during the decade, but many

of those which were in that category in 1937 were still among the leaders in 1946. The following list shows the evening programs at the top of the popularity parade at the end of six of the ten years, as rated by C.A.B. through its polls of listeners:

1937	1939
1. Chase and Sanborn program (Edgar Bergen, etc.)	1. Chase and Sanborn program
2. Jack Benny	2. Jack Benny
3. Major Bowes' Amateur hour	3. Lux Radio Theatre
4. Kraft Music Hall (Bing Crosby)	4. Fibber McGee and Molly
5. Eddie Cantor	5. Kraft Music Hall
6. Lux Radio Theatre	6. Major Bowes
7. Town Hall Tonight (Fred Allen)	7. Bob Hope
8. Rudy Vallee	8. Fitch Bandwagon (Guest orchestras)
9. Burns and Allen	9. Kate Smith Hour
10. Hollywood Hotel	10. Pot o' Gold
1941	1943
1. Chase and Sanborn program	1. Fibber McGee and Molly
2. Jack Benny	2. Bob Hope
3. Fibber McGee and Molly	3. Chase and Sanborn program
4. Lux Radio Theatre	4. Jack Benny
5. Aldrich Family	5. Lux Radio Theatre
6. Bob Hope	6. Red Skelton
7. Maxwell House Coffee Time	7. Aldrich Family
8. Walter Winchell	8. Maxwell House Coffee Time
9. Kate Smith Hour	9. Mr. District Attorney
10. Fitch Bandwagon	10. Kay Kyser
11. Kraft Music Hall	
1944	1945
1. Bob Hope	1. Bob Hope
2. Fibber McGee and Molly	2. Fibber McGee and Molly
3. Jack Benny	3. Edgar Bergen, Charlie McCarthy, etc.
4. Walter Winchell	4. Lux Radio Theatre
5. Kraft Music Hall	5. Jack Benny
6. Seafest Village Store	6. Fred Allen
7. Chase and Sanborn program	7. Red Skelton
8. Lux Radio Theatre	8. Mr. District Attorney
9. Mr. District Attorney	9. Walter Winchell
10. Screen Guild Players	10. Eddie Cantor
11. Abbott and Costello	

The predominance of serial dramas in daytime schedules was evident in the lists of the most popular daytime programs. The following list shows the leaders in C.A.B. appraisals of daytime shows during the latter months of each year:

1937	1939	1941
1. Guy Lombardo	1. Ben Bernie	1. Life Can Be Beautiful
2. Today's Children	2. Ma Perkins	2. Kate Smith Speaks
3. Ma Perkins	3. Hobby Lobby	3. Woman in White
4. Vic and Sade	4. Pepper Young's Family	4. Right to Happiness
5. The O'Neills	5. Vic and Sade	5. Romance of Helen Trent
6. Pepper Young's Family	6. Guiding Light	6. Our Gal Sunday
7. David Harum	7. Mary Marlin	7. Guiding Light
8. Just Plain Bill	8. Woman in White	8. Ma Perkins
9. Magic Key of RCA	9. Stella Dallas	9. Road of Life
10. Big Sister	10. Goldbergs	10. Mary Marlin (Vic and Sade)
	11. Road of Life	
1943	1944	1945
1. Kate Smith Speaks	1. When a Girl Marries	1. Breakfast in Hollywood (11 A.M., E.S.T.)
2. Stella Dallas	2. Kate Smith Speaks	2. Portia Faces Life
3. Big Sister	3. Ma Perkins (CBS)	3. When a Girl Marries
4. Pepper Young's Family	4. Breakfast at Sardi's (Kellogg)	4. Big Sister
5. Right to Happiness	5. Our Gal Sunday	5. Pepper Young's Family
6. Backstage Wife	6. Romance of Helen Trent	6. Young Widder Brown
7. Ma Perkins (CBS)	7. Portia Faces Life	7. Ma Perkins (CBS)
8. Young Widder Brown	7. Breakfast at Sardi's (Procter and Gamble)	8. Breakfast in Hollywood (11:15 A.M., E.S.T.)
9. Romance of Helen Trent	8. Big Sister	9. Breakfast Club (9:30 A.M., E.S.T.)
10. Our Gal Sunday	9. Stella Dallas	10. Ma Perkins (ABC)
11. Lorenzo Jones	10. Pepper Young's Family	

U.S. Trends.—Year by year, notable developments in U.S. radio programming during the decade included the following:

In 1937 the audience-participation program, best typified by the "Major Bowes' Amateur Hour," emerged as a dominant type. The trend toward development of movie talent programs originating in Hollywood continued and was recognized early in the year as a major factor in network operations. Dramatic programs were increasing. Political parties used radio more than ever before to com-

mand larger audiences. "Educational radio" received greater emphasis both in quantity and quality of programs. Greater effort was spent to make the broadcasts entertaining as well as instructive. Among the leaders in this field during 1937 were George V. Denny's "Town Hall of the Air," a series of debates on problems of the day conducted by recognized authorities with the audiences invited to participate by submitting questions from the floor; and the Columbia Broadcasting system's "American School of the Air," which was required listening in many schools. To such outstanding programs as these were added many worth-while dramatizations sponsored by the U.S. office of education as the federal government entered the field of radio education.

In 1938 rehearsals for radio's later wartime role were provided in two major international crises: the German annexation of Austria in March, and the Czechoslovakian crisis six months later. Several new and improved radio techniques were used to accomplish rapid, comprehensive coverage of events.

The Mutual Broadcasting system broadcast recordings of official news reports received by short wave from European news centres. The Columbia Broadcasting system utilized its "European Roundup" to bring listeners concise, on-the-spot accounts direct from its own or newspaper correspondents overseas. A C.A.B. survey showed that on Sept. 28, 1938, the day before the Munich conference, one out of every six programs heard was a news broadcast. The most sensational program of the year was the "Mercury Theatre" broadcast on Oct. 30 when Orson Welles dramatized H. G. Wells' *War of the Worlds* and terrified thousands who accepted as fact his description of an invasion of New Jersey by warriors from Mars.

The speed of radio in bringing news into the homes of its listeners was demonstrated repeatedly during the tense months preceding and following the start of World War II in 1939. Americans learned that war had been declared even before the news reached the German people, hearing it from Britain's Prime Minister Neville Chamberlain in a speech received in the United States at 6 A.M. (New York time) on Sept. 3, while Berlin commentators, heard in broadcasts picked up by U.S. networks following the Chamberlain speech, were still talking of hopes for averting war with England. On that day as many as 78 newscasts were carried on one network alone.

With war an actuality, the always-present radio problems of time and distance were complicated by another major difficulty: that of sorting facts from propaganda. To help guard U.S. neutrality, the nation's major networks on Sept. 11 voluntarily agreed to move cautiously in handling European news, adopting the motto: "When in doubt, don't; there is always time to check."

The first on-the-scene war broadcasts from U.S. radio correspondents reached the American people in mid-Oct. 1939. On Oct. 9 the first contingent of U.S. war correspondents officially accredited by British military authorities left London for "somewhere in France." In the group were Bill Henry of Columbia Broadcasting system and Arthur Mann of Mutual Broadcasting system, two of the first radio reporters ever assigned to front-line duty.

Radio presented many outstanding special-events broadcasts during 1939, from the address of President Roosevelt at the opening of congress on Jan. 4 to a dramatic eyewitness account of the scuttling of the German battleship "Graf Spee" in late December. The year's schedule included a description of the funeral ceremonies of Pope Pius XI and the coronation of Pope Pius XII; the sinking of the submarine "Squalus"; an address by the Duke of

Windsor; the visit to America by Britain's king and queen; the president's address at the opening of a special session of congress and the opening of the world's fairs in New York and San Francisco.

The presidential election year of 1940 brought campaigners to the microphone in greater numbers than ever before, starting with the Republican National convention in June and the Democratic convention a month later. Wendell Willkie's Elwood, Ind. speech accepting the Republican presidential nomination won the highest listener rating (37.8%) ever accorded a political broadcast in a C.A.B. survey up to that time. But President Roosevelt held a consistent edge over his opponent in audience appeal, especially in the closing days of the campaign. His Oct. 30 speech from Boston was rated 38.7% by C.A.B.

War news continued to occupy a significant portion of the broadcast day throughout 1940. With Germany's unexpected drive into Scandinavia in April, radio moved into an "emergency" status to provide coverage of the new front. When Italy entered World War II on June 10, the concentration of speeches by national leaders surpassed anything since the outbreak of hostilities on Sept. 3, 1939. President Roosevelt's June 10 speech at Charlottesville, Va., in which he denounced the "stab in the back" by Italy, received a rating of 45.5%, the highest mark recorded by C.A.B. for a speech of any kind up to that time.

In the entertainment field, the trend was toward shorter and less formal programs. Expensive variety shows, usually built around "name talent," gave ground to less expensive programs of the quiz type. Thirty-three audience-participation programs appeared on the networks. Drama also moved ahead. Variety shows remained at the top in both time and popularity, but by a smaller margin. The Federal Communications commission (FCC) announced on March 29, 1940, its belief that five contest programs, of the cash "give-away" type, violated the section of the Communications act which prohibited lotteries. The justice department later ruled, however, that the cases were not prosecutable.

The Japanese bombing of Pearl Harbor on Dec. 7, 1941, and subsequent developments, demonstrated more fully than ever before that events, rather than the leading commercial programs, might be the yardstick of maximum audience size. The president's Dec. 8 appeal for declaration of war against Japan was rated by C.A.B. at 65.7%, and his address the following night broke all records for nighttime listening with a rating of 83%. Prime Minister Winston Churchill's voice also became familiar to U.S. listeners during 1941, attracting substantial audiences in broadcasts from Britain and, during a December visit, from the United States. His best C.A.B. rating was 44.7% for a noontime broadcast on Dec. 26.

The scope of radio's coverage of the war in Europe had been extended once again in 1941 by Germany's surprise declaration of war on the U.S.S.R. in June. Newscasters, like news listeners, were caught napping, but scurried to their microphones in various stages of dress from pajamas to evening clothes. From then onward, the progress of the soviet campaign was a part of virtually every news broadcast.

The restraint which characterized most British radio programming, and the matter-of-fact calmness of its news reporting, were demonstrated by the British Broadcasting Corp. (BBC) on the first day of 1941. During an attack by German planes, Broadcasting house in London was bombed and seven BBC employees were killed, but the announcer on the air at the time went ahead with his commentary without a break, never mentioning the direct

hit or deviating from the prepared script.

On the last day of 1941, the radio in Manila fell silent. To prevent their falling into the hands of the Japanese, all broadcast stations in the city were dismantled and destroyed by their owners. (The silence lasted until U.S. radio returned to the air in Manila in Feb. 1945, with the liberation of the city.)

During 1942 several trends appeared in radio programming, many of them resulting largely from wartime operation. War-effort programs were in the forefront, presented by the networks (more than half were sustaining), by government agencies and departments working through the Office of War Information's (OWI) new and elaborate radio branch, and by the advertisers. To mobilize the government's advertising campaign, the Advertising council (later the War Advertising council) was formed in February, and seven months later the army set up a top radio performers' "Committee of 25" to broadcast and tour military installations in behalf of radio. In October, OWI Director Elmer Davis estimated that radio was contributing \$64,000,000 worth of time to the war effort annually. At year's end it was estimated that the major networks devoted more than 4,000 network hours to war-effort programs and announcements during 1942.

Reflecting the first major change in listener preference in the radio-entertainment field since the rise in popularity of audience-participation programs, the comedy drama emerged as an audience favourite, filling 10% of all network evening time during the year. In the daytime schedule, considerable controversy developed about the so-called "soap operas," but unrelenting sponsor support resulted in their retention for the most part, although several series were discontinued. A reversal of the former movies-to-radio trend among entertainers also became apparent in 1942, as old-time radio stars began to show up in some of the leading screen plays. Abbott and Costello, radio stars before they went into motion pictures, were the top box office attraction of the movies in 1942. Other top-flight motion picture actors who starred in radio before they received Hollywood calls included Bob Hope, Bing Crosby and Jack Benny. The talent costs of network commercial programs were estimated by trade sources at approximately \$35,000,000 for nighttime programs and \$8,000,000 for daytime programs.

Throughout 1943 the emphasis on war programming continued, and many commercial programs made regular use of war effort and public service themes. The radio branch of the OWI, which cleared all programs in the war-effort category, estimated in March that radio had donated \$86,900,000 in time and talent—\$71,570,000 and \$15,330,000 respectively—to war-effort messages alone. A regular weekly schedule of campaigns was inaugurated and became evident in the number of special announcements and programs which appeared both on the networks and on individual stations throughout the country.

The year 1943 saw an increase in the number of international pickups employed by the networks, with more broadcasts direct from the theatres of war. All networks expanded their war news staffs. The wire recorder, a lightweight instrument using a magnetized wire for recording and reproduction, came into prominence in war reporting; dispatched to the fighting fronts through the war department's radio branch, it was used for many outstanding programs employing actual pickups from battle zones. In the unconditional surrender of Italy to the Allies in September, radio was given a new war role as General Eisen-

lower broadcast the announcement to the world.

From the standpoint of entertainment, 1943 was a year of new programs, with all types except classical and semi-classical music represented among the newcomers. Many entertainers from other fields, including such established comedians as Groucho Marx and Jimmy Durante, were given featured programs. "Grand Ole Opry," a variety show of the "hillbilly" type, was promoted from regional to coast-to-coast status. New offerings in melodrama included "Suspense," added as a sustaining program. Familiar and popular music were represented in a large number of new shows, and new dramatic productions ranged from such dramatized war stories as "The Man Behind the Gun" to another revival of "Sherlock Holmes."

The average daytime audience for network productions attained an all-time high during 1943, according to C. E. Hooper Inc., radio research organization. The volume of daytime serials remained constant at about 50 hours per week, but weekday non-serial programs surged upward from 6½ hours to 22¾ hours a week between January and December. Network talent costs continued to increase during the year, generally as a result of widespread introduction of union scales for performers and announcers. Trade estimates placed talent costs of network commercial programs at about \$40,000,000 for nighttime programs and \$8,000,000 for daytime programs.

In the following year (1944), radio's attainments in news coverage again kept pace with the armed forces' military achievements, notably in reporting the landings in France and in describing General MacArthur's return to the Philippines. In preparation for the invasion of Europe, the networks for the first time pooled their facilities, and during the early days of the operation virtually all broadcasts were for the use of all networks. One of the most spectacular, used on all networks and frequently rebroadcast, was one recorded by George Hicks, American Broadcasting Co. commentator, aboard a landing craft under attack by German planes as it moved toward the coast of France. Such major networks as the National Broadcasting Co. and the Columbia Broadcasting system dropped their bans on recorded broadcasts to carry similar running descriptions of invasion operations.

With the D-day landings on June 6, radio added a new phase to its war service. A radio transmitter was landed on the beachheads and used immediately to establish communication not only across the channel to Britain but direct to the United States. Regular radio units were set up with the armed forces, and the American Broadcasting system in Europe (ABSIE), using high power, was established to broadcast direct to the troops in occupied territory. In the Pacific, news of the October invasion of the Philippines by General MacArthur's troops was relayed throughout the world from a radio ship rigged for the purpose and maintained later as the radio operating base in that theatre.

The 1944 presidential election campaign, conducted primarily by radio, brought political oratory to the air in the greatest volume in history. It was estimated that each party spent about \$1,500,000 for radio time, exclusive of repayment of talent which was displaced. In audience appeal as in votes, President Roosevelt led his opponent, the C.A.B. average ratings being 24.4% for Roosevelt and 16.7% for Governor Thomas E. Dewey. In a nonpolitical, invasion eve speech on June 5, keyed to the fall of Rome, President Roosevelt attracted 96.9% of all sets in use, according to the C.A.B.

Radio's time and talent contributions to the war effort increased steadily. The National Association of Broadcasters estimated that the total reached \$161,752,000 in 1944, distributed as follows: Radio advertisers \$64,000,000; stations and networks \$78,000,000; talent \$20,000,000. This was an increase of 8% over 1943 totals. Although no accurate data were computed covering aggregate talent costs of network commercial programs, industry estimates indicated a continuation of the previous years' upward trend, putting the figures in the neighbourhood of \$45,000,000 for nighttime programs and about \$10,000,000 for daytime shows.

Military victory in 1945, first in Europe and later in the Pacific, brought a deluge of special-events broadcasts and lifted listening to the highest peaks since the United States had declared war against Japan. By coincidence the peak audiences on both victory days were identical—63.1% of all receiving sets in use, according to surveys by C. E. Hooper Inc. Twice during the year all normal network schedules were cancelled and special broadcasts were substituted: first, upon the death of President Roosevelt, the nation's "first radio president," on April 12; and again four months later, on Aug. 14, with the end of the war against Japan. The same was true to a lesser extent on V-E day, May 8, which networks followed with special programs on the victory theme at a time and talent expenditure of approximately \$1,000,000. One of the outstanding programs of the year was Norman Corwin's "On a Note of Triumph," broadcast on the Columbia Broadcasting system as part of the V-E day celebration.

On Sept. 1, 1945 (U.S. time), the official ceremonies of Japan's surrender were recorded aboard the U.S. battleship "Missouri" in Tokyo bay and broadcast on all networks, after being held up for 90 minutes by transmission difficulties. Other listening highlights of 1945 revolved around the inauguration of President Roosevelt for his fourth term and later the inauguration of President Truman; the first use of the atomic bomb and the U.S.S.R.'s entry into the war against Japan; the sessions of the United Nations Conference on International Organization in San Francisco, and, after the end of World War II, the lifting of many wartime controls and the first steps toward reconversion of the civilian economy.

The fall season of 1945 saw the greatest influx of new programs in radio history, reflecting the change to a peacetime advertising perspective, the development of new program ideas and the return of many old radio favourites from war service or war-related employment. New programs which achieved popularity included the "Danny Kaye Show," "Theatre Guild on the Air," "Request Performance," "This Is Your FBI" and "Textron Theatre." In the daytime ranks, Fred Waring and his orchestra found popularity as a sustaining program, and "Queen for a Day" and "Ladies Be Seated" were among the most popular new commercial programs. A survey conducted by *Broadcasting* found that most stations were devoting 15% to 20% of their broadcast time to news, compared with about 5% before the war, and that they expected to maintain the increased volume of news shows in peacetime. Talent costs of network commercial shows continued to rise in 1945 and were estimated at approximately \$50,000,000 for evening programs and \$10,000,000 for those carried in the daytime.

More local news, more local live-talent programs, and more emphasis on "public-interest" programs were among the major trends of 1946 as found in a survey conducted for *Broadcasting* by Audience Surveys Inc., an independent research organization. Results of the survey, published in

December, showed that 76% of the reporting stations spent an average of 24% more money on programming in 1946 than in 1945. Only 2% spent less. Another dominant trend was in the application of stricter controls over the length and content of commercial announcements, reflecting a natural reaction from wartime use of innumerable and often lengthy messages for government agencies and departments in support of the war effort.

A network program innovation of major stature in 1946 was the use of transcriptions, rather than live broadcasts, by one of the most popular entertainers in radio, Bing Crosby. The first major experiment in transcribed network programs, the opening broadcast of the series, on Oct. 2, won a listener rating of 23% from C. E. Hooper, Inc. A month later the rating skidded to 12.2%, but moved up to 15.8% in mid-November. If successful, the transcribed method was expected to be adopted by many other top-flight entertainers.

The whole question of whether or to what extent radio stations should be required to make appropriate identifying announcements when transcriptions or recordings were used on programs was made the subject of a hearing before the Federal Communications commission in late November. It was not linked with the Crosby series, however, having been initiated by the commission in June through a proposal to liberalize substantially its requirements for such announcements.

The Columbia Broadcasting system, the National Broadcasting Co. and larger stations generally opposed the liberalization plan, arguing that listeners would be deluded unless specifically told when transcriptions were used, and that recordings would gradually replace the far more costly live-talent shows. American Broadcasting Co., which carried the Crosby series, favoured the plan, as did many smaller stations and independent outlets which lacked the resources of large stations and relied heavily upon recordings and transcriptions to build up their audiences. The issue was decided in early December by a FCC ruling that stations must continue to tell listeners when recordings were used if the recordings were more than one minute in length, but waiving the requirement for recorded material up to one minute's duration.

Comedy and variety programs continued to hold a great share of radio time and radio audiences in 1946, with serial stories continuing to dominate the daytime popularity ratings. The C. E. Hooper report for mid-November showed Jack Benny in first place, Bob Hope in second and Edgar Bergen and Charlie McCarthy in third. The daytime list was led by "Right to Happiness," "When a Girl Marries" and "Aunt Jenny," all serial dramas.

A full schedule of special-events broadcasts was carried during 1946, including descriptions of the atom bomb tests in the Pacific, features as well as straight news and commentaries from the United Nations meetings, and detailed coverage of the off-year election landslide which returned the Republican party to control of house and senate. President Truman used radio frequently; C. E. Hooper, Inc. reported that he was heard by 25,217,000 persons in a May 24 speech on the railroad strike, and by 23,166,000 in an address on his veto of the first OPA bill in July. (For FM and television programming, see under *Growth and Developments*, page 702; see also Music.)

Commercial Broadcasting

The United States remained by all odds the world's foremost practitioner of free, commercial radio. Although no comparative data on their financial operations were available, it was known that the radio systems of all other

countries fell far short of the industry in the United States from the standpoints of both revenues and expenditures. Among U.S. networks and stations, total revenues from the sale of time increased approximately 163% during the decade; expenditures rose 135% and broadcast income (representing revenues less expenses, before payment of federal taxes) climbed 274%.

By way of comparison, Great Britain's British Broadcasting Corp. (BBC), which in point of programming perhaps was noncommercial radio's closest approach to radio in the United States, was reported to have received and spent approximately \$35,000,000 during the year ended March 1, 1945, while U.S. networks and stations reported revenues approaching \$300,000,000, expenses exceeding \$215,000,000 and a "net income" of more than \$83,500,000 during a comparable period.

U.S. Revenues, Expenses, Income.—Aggregate figures on U.S. time sales, revenues (after payment of agency commissions on time sales), total broadcast expenses aside from commissions, and the resultant broadcast income before income taxes were as follows for the period 1937-45, inclusive, based on compilations prepared by the FCC from annual reports filed by stations and networks:

Total time sales: \$1,717,843,408.
Total revenues: \$1,633,971,184.
Total broadcast expenses: \$1,205,823,294.
Total broadcast income: \$428,147,890.

Networks and their key stations—exclusive of the hundreds of affiliated and independent stations—increased their annual broadcast or "net" income per year from \$7,719,213 to \$18,046,722 during the ten-year period.

A year-by-year breakdown of revenues, expenses and broadcast income during the decade is provided in Table I, based on FCC reports. Commissions paid to agencies for the sale of time were deducted before figures on "revenues" were prepared, and, therefore, were not counted as "expenses." The figures on "broadcast income" were computed before payment of federal income taxes.

Table I.—U.S. Broadcast Revenues, Expenses, and Income
1937-45, inclusive
(000's omitted)

Year	Number of stations	Revenues	Expenses	Broadcast income
1937	629	\$114,010	\$91,656	\$22,354
1938	660	111,358	92,503	18,854
1939	705	123,881	100,043	23,837
1940	765	147,146	113,850	33,296
1941	817	168,779	123,940	44,839
1942	851	178,839	134,207	44,632
1943	841	215,317	148,842	66,475
1944	875	275,298	185,025	90,272
1945	901	299,338	215,753	83,584

Note: The number of stations listed for each year is the number which filed financial reports with FCC; a few stations in each instance failed to report. Figures for 1938 and 1939 include operations of three national networks; those for 1940 and 1941, three national and five regional networks; 1942 and 1943, four national and six regional networks; 1944 and 1945, four national and five regionals.

As shown by Table I, the upward trend of broadcast expenses was never interrupted between 1937 and 1945, while revenues increased consistently after a momentary lapse in 1938. In three years of the ten, however, the rate of increase in costs surpassed the increase in revenues, with a falling off resulting in broadcast income. The first occurred in 1938, a drop of about 15% below the 1937 level. The second, in 1942, was almost negligible, amounting to about 0.5%. The third, in 1945, was a 7.3% slump which FCC officials attributed partially to the number of new stations which at best had not reached "normal" operating incomes and which consequently encountered losses in some instances.

Average Broadcast Income.—A half-decade summary of

the growth of average station income was provided in a report issued by the FCC in late 1946. Data from the stations' past financial reports were broken down to show average income of stations in all power classes as well as the average for all stations, starting in 1941, as reflected in Table II.

Table II.—Average U.S. Broadcast Incomes, 1941-45, Inclusive
(000's omitted)

Class of Station	1941	1942	1943*	1944*	1945*
Clear channel:					
50-kw. full-time	\$370	\$331	\$400	\$496	\$458
50-kw. part-time	121	143	221	305	193
5-20-kw. full-time	28	38	61	129	101
5-20-kw. part-time	43	52	50	127	110
Regional:					
Full-time	\$54	\$52	\$79	\$114	\$106
Part-time	15	9	18	35	37
Local:					
Full-time	\$4	\$4	\$12	\$23	\$22
Day and part-time	4	3	7	10	10
All Stations†					
(Complete figures)	\$40,928	\$38,705	\$55,981	\$80,266	\$73,555

*Data for 1943, 1944 and 1945 do not include the operations of key stations of national networks, as reports filed by them with FCC do not include adequate segregations of expenses between station and network operations.

†This table covers the operations of 817 stations in 1941; 851 in 1942; 832 in 1943; 865 in 1944 and 891 in 1945.

Time Sales.—Time sales by networks and stations, the mark of radio's acceptance as an advertising medium as well as its chief support (representing 90% to 95% of all revenues), increased during every year of the decade, as shown in Table III, prepared from FCC records. Figures are before deduction of commissions paid to agencies, etc., which broadcasters considered an expense of sale.

Table III.—Total U.S. Time Sales, 1937-45 Inclusive
(000's omitted)

Year	Network Sales Retained By Networks	Revenues from Station Time Sales To Networks and Stations	To National and Regional Users	To Local Users	Totals
1937	\$35,812	\$22,141	\$23,117	\$36,838	\$117,908
1938	35,455	21,157	28,109	33,402	118,124
1939	38,809	24,114	30,472	37,315	130,711
1940	45,194	28,603	37,140	44,756	155,694
1941	49,554	32,092	45,681	51,697	179,027
1942	55,058*	30,130	51,059	53,898	190,147
1943	65,350*	39,294	59,352	64,104	228,102
1944	77,342†	52,027	73,312	84,960	287,642
1945	81,364†	52,609	76,696	99,814	310,484

*Includes operations of nine key stations of networks.

†Includes operations of ten key stations of networks.

Gross Billings.—Additional evidence of the advances made in over-all time sales during the decade was found in the figures on gross billings, which among broadcasters were a popular gauge of advertising volume. Gross billings differ from preceding reports on time sales in that they are computed on the basis of charges for a single broadcast, without deductions for frequency of use of a station's or network's facilities. *Broadcasting* magazine estimated annual gross billings during the decade as in Table IV.

Table IV.—Estimated U.S. Gross Billings, 1937-45 Inclusive
(000's omitted)

Year	National Network	Others	Totals
1937	\$68,828	\$75,314	\$144,142
1938	71,728	78,390	150,118
1939	83,114	88,000	171,114
1940	96,456	111,500	207,956
1941	106,900	130,700	237,600
1942	118,200	136,600	254,800
1943	151,791	155,400	307,191
1944	190,677	201,200	391,877
1945	199,580	220,800	411,547

Incidental Revenues.—Although time sales normally accounted for the bulk of the industry's revenues, the increase in funds received from other sources—from the sale of talent, booking commissions, etc.—more than kept pace

with the rapid rise of time sales, approximately quadrupling between 1937 and 1946. Incidental revenues in 1937 were reported at about \$8,000,000. By 1940 they had grown to \$13,181,948. In 1942 they reached \$15,196,554. The following year they totalled \$19,613,621; in 1944, \$28,959,072 and in 1945 \$32,777,553.

Losses.—While broadcast income increased during the decade, the number of "losing" stations dropped appreciably and average losses followed a similar downward trend with two exceptions.

In 1939 227 of 705 reporting stations experienced losses aggregating \$2,220,471, an average of \$9,783 per losing station, according to FCC records. The following year, 187 of the 765 operators reported a combined loss of \$1,551,812, an average of \$8,298. In 1941 losing stations numbered 174 out of 817 reporting; their combined loss was \$553,440, their average loss \$3,180. Two years later the number of "losers" dropped to 94 of 841 stations for a combined loss of \$502,000, but the average rose to \$5,348. In 1944 41 of 875 stations lost \$154,310, averaging \$3,764, and in 1945 a total of 50 out of 901 showed losses aggregating \$643,006, which pushed the 1945 average loss up to \$12,860.

Tangible Property.—With the year-to-year addition of new stations, and improvement and expansion of others, the original investment in stations and associated broadcasting equipment moved up from \$46,240,128 in 1937 to \$72,281,223 in 1945, according to FCC compilations, while depreciated costs rose from \$25,795,104 to \$34,546,328. These figures related only to stations—613 in 1937 and 891 in 1945.

In addition, in 1945 the original cost of the tangible broadcast property of 4 nationwide networks and their 10 key stations was reported as \$15,699,154, and that of 3 regional networks as \$121,563, for a total of \$88,101,940. Depreciated costs of the major networks and their keys during 1945 were listed as \$6,983,190; 3 regional networks, \$65,501, and industry total, \$41,595,019.

In other years of the decade, valuation of tangible property in use in the industry had a composition as shown in Table V, from FCC records.

Table V.—Tangible Property of the U.S. Broadcasting Industry
(000's omitted)

Owner	1940		1943		1944	
	Orig. Cost	Deprec. Cost	Orig. Cost	Deprec. Cost	Orig. Cost	Deprec. Cost
Stations*	\$57,811	\$31,978	\$67,151	\$35,415	\$68,466	\$34,050
Major networks	\$11,920	\$7,373	\$13,884	\$6,645	\$14,418	\$6,433
Regional networks	\$1,184	\$702	\$112	\$75	\$112	\$68
Totals in complete figures:						
Original cost	\$70,916,312		\$81,148,128		\$82,997,650	
Depreciated cost	\$40,055,112		\$42,136,777		\$40,552,273	

*Figures on stations represent 765 in 1940; 832 in 1943; 865 in 1944.

Growth and Developments

Both frequency modulation (FM) and television won recognition as practical operations (although television was not yet a profitable one) during the decade 1937-46, and both made sensational gains, particularly in the United States in the postwar years. But from the standpoint of numbers, on a world-wide basis, standard or amplitude modulation broadcasting (AM) outdistanced all other branches of the radio art in growth.

Standard Broadcasting.—Compilations by *Broadcasting* from information supplied by the U.S. department of commerce and other official sources, including in some cases reports from the nations themselves, showed approximately 2,300 broadcasting stations known to be on the air in

Above: Company of the Metropolitan Opera of New York during a presentation of *Aida*. Saturday afternoon broadcasts from the "Met" continued to be one of the outstanding musical offerings in radio between 1937 and 1946

Upper right: "When a Girl Marries," a U.S. serial drama which had more listeners than any other daytime program during 1944 and 1945, according to Hooper ratings. Mary Jane Higby and Robert Haag of the cast are shown at the microphone

Right: Arturo Toscanini conducting the NBC symphony orchestra. Concert music filled 3.2% of evening radio time on the U.S. networks in 1946

Lower right: "Truth or Consequences," a popular U.S. audience-participation program

Below: Guests of the University of Chicago Round Table, Chicago, Ill., continued to offer timely debate on current affairs throughout the decade 1937-46

1937. These included long-wave, medium-wave and short-wave stations. For some nations the totals were known to be incomplete; in Spain, for instance, the civil war of 1936-39 made it impossible to obtain accurate figures, while in China the occupation by Japanese troops posed a similar barrier to complete reporting.

In 1946 the war-born Foreign Broadcast Intelligence service (FBIS) of the U.S. war department, formerly a branch of the FCC, published a list of approximately 3,365 long-wave, medium-wave and short-wave stations known to be in more or less regular operation throughout the world, excluding approximately 1,500 medium-wave stations in operation or authorized in the United States. With these, the total was 4,865.

Comparatively, these figures were useful in providing a general picture, rather than an exact comparison, of broadcasting stations in operation in 1937 and again in 1946. The latter total, for example, included relay stations, which for the most part were excluded from the 1937 compilation. It also included stations which were seasonally inactive, and those whose frequencies were found to vary over a long period of time, usually owing to transmitter instability or to attempts to escape chronic interference. Hundreds of the total number were stations set up by Allied forces in occupied countries to serve occupation troops and civilian populations, and many of these eventually would be discontinued. The total did not include stations which were off the air, a particularly frequent development among stations in battlefield countries.

Any error in the two compilations, however, apparently was on the conservative side. While the absence of uniform reports from all nations left the 1937 list incomplete, similar problems arose in 1946 (primarily in regard to the Manchurian situation), and at year's end, FBIS had a new list in preparation which spokesmen said would show even more stations than the number previously reported.

For purposes of general comparison only, the number of stations reported for geographical areas of the world during the two terminal years of the decade is shown in Table VI. To provide a somewhat better comparison, the figures for 1946 do not include those of any nation which either had no stations in 1937 or reported none. Thus the table shows the increase on an "identical nations" basis.

Again counting short-wave as well as medium-wave and long-wave stations, with 1946 figures including relays and stations operated by Allied nations in occupied countries, the breakdown according to nations included the following (the list shows leading or typical countries within continents and is therefore not a list of the leaders of the entire world from the standpoint of number of stations):

Country	1937	1946
United States	734	1,632
U.S.S.R.	77*	310
Mexico	102	249
Japan†	40	173
Australia	112	162
Canada	83‡	159
Brazil	55	128
Chile	64	119
Colombia	47	114

Africa	39	97	11

*Includes relay stations.

†Figures are for U.S., Canada, Alaska; do not include Canadian short-wave stations in 1937.

‡Report incomplete for Spain, owing to civil war.

§Report incomplete for China, owing to military occupation and seizure of stations.

In the United States, the number of standard, or amplitude modulation, broadcasting stations grew from 721 at the end of 1937 to approximately 1,500 at the end of 1946, including those authorized and under construction as well as those in operation. The bulk of this increase came in the 14 months after the government's wartime restrictions on licensing and construction were lifted on Oct. 8, 1945. In late 1946 FCC officials estimated that they had licensed an average of one new AM station a day since V-J day.

The gain in the number of broadcasting stations in the U.S. was relatively steady from 1937 through 1942, the first full year of U.S. participation in World War II. Thereafter the advance was slowed by increasingly strict limitations on building. In 1942 for the first time in the ten-year period, the number of stations showed a decline. Another slight drop occurred in 1943. In both instances the lapses were attributed not alone to the construction bans but to the fact that a few stations, unable to cope with the military demand for skilled technical personnel, voluntarily ceased operations. For the most part, wartime licensing of new stations was permitted only in areas regarded as underserved from a military standpoint, with some further easings of restrictions in 1944.

The following list, from FCC records, traces the growth of AM broadcasting stations in the U.S. during the 1937-46 decade. Figures show the number on Dec. 31 of each year.

1937	721
1938	764
1939	814
1940	882
1941	923
1942	917
1943	912
1944	943
1945	1,004
1946*	1,500

*Estimated.

Listeners.—Radio receiving sets throughout the world increased from approximately 80,000,000 in 1937 to 125,000,000 at the end of the ten-year period. The United States consistently reported almost half of the world's total.

The leading 25 countries of the world in point of receivers in 1946 and the number of sets they reported in 1937 are shown in Table VII. The 1946 figures were released Jan. 1, 1947, by Caldwell-Clements, Inc., publishers, and *Tele-Tech* magazine, and unless otherwise indicated are for the year 1946. The 1937 figures were compiled by *Broadcasting* from information supplied by the U.S. department of commerce and other official sources.

In the United States, the decade's increase in receivers was from 37,600,000 to approximately 60,000,000. The FCC estimated unofficially that the number of sets in the nation in late 1946 approached 66,000,000. But even on the basis of the more conservative figure reported by Caldwell-Clements, Inc., the decade's gain amounted to more than 59%. Year by year, the increase is shown in Table VIII prepared for *Broadcasting* by O. H. Caldwell, of Caldwell-Clements, Inc.

The number of radio homes in the United States—those

Table VII.—Radio Sets in Use

Country	1937	1946
United States	37,600,000	60,000,000
Great Britain, Northern Ireland	8,347,800	10,673,000
Russia	3,938,000 (1939)	10,551,361*
France	4,018,992	5,376,000
Germany	8,285,193	5,500,000†
Japan	3,434,172	4,500,000‡
Sweden	1,041,737	1,858,614
Canada	Not reported	1,754,351
Italy	800,000	1,500,000
Australia	985,983	1,479,802 (1945)
Czechoslovakia	985,500	1,433,896
Argentina	1,000,000	1,300,000
Brazil	420,000	1,200,000
Denmark	689,389	1,009,802

Hungary	376,596	200,000§
Switzerland	500,000	867,365
Austria	612,142	820,000
Belgium	976,343	700,000
Mexico	325,000	600,000
Finland	210,000	516,732 (1945)
China	No data available	500,000¶
Manchukuo	112,771 (1938)	500,000 (1944)
New Zealand	274,911	375,453 (1944)
Spain	500,000 (1938)	375,365

*Includes 6,110,000 loud-speakers connected to relay exchanges.

†14,000,000 in 1944; in all cases it is well to consider the effect of war on receiver totals in battlefield countries.

‡7,000,000 in 1943.

§904,176 in 1944.

||Includes 118,095 "wired wireless" connections.

¶Estimates vary between 350,000 and 2,000,000.

Table VIII.—Sets in Use in the United States
(1937-46, inclusive)

1937	37,600,000
1938	40,800,000
1939	45,300,000
1940	51,000,000
1941	56,000,000
1942	59,340,000
1943	57,000,000*
1944	55,000,000*
1945	56,000,000
1946	60,000,000

*The decline in 1943 and again in 1944 resulted from wartime bans which virtually halted production of radio receiving sets and replacement parts for civilian use.

with one or more receivers in operating condition or temporarily out of order because of missing tubes or other parts—rose from 26,666,500 in 1937 to 29,700,000 in 1941 and on up to 34,000,000 in 1945 and 35,000,000 in 1946.

Of the total sets in use in the nation, automobile radio receivers comprised 5,000,000 in 1937, 8,500,000 in 1941, approximately 8,750,000 in 1942 and 6,000,000 in 1945 and 1946.

The decline was attributed to the wartime cessation of production of both receivers and automobiles for civilian use.

Caldwell-Clements, Inc. broke down their 1946 world-wide figures on receiving sets as follows:

United States homes with radios	35,000,000
Secondary sets in these homes	15,000,000
Sets in business places, institutions, etc.	4,000,000
Automobile radios	6,000,000
Total sets in the United States	60,000,000
Total sets in the rest of the world	65,000,000
Total sets in the world	125,000,000

Frequency Modulation.—Frequency modulation (FM), the static-free form of broadcasting patented in 1933 by Edwin H. Armstrong, professor of electrical engineering at Columbia university, remained an experimental operation until Jan. 1, 1941. At that time, pursuant to an authorization adopted by the FCC in May 1940, operation of FM on a commercial basis was inaugurated. There were then 29 authorized commercial FM stations.

The total reached 62 early in 1942, but the infant art became a wartime casualty when military needs imposed a virtually complete ban on production of both station equipment and receiving sets, and on construction of buildings to house new stations. The number of authorized outlets dropped to 47 by early 1943, as many permittees gave up their grants for want of materials with which to go ahead. At the outset of 1944 authorizations totalled 50, and a year later they reached 62, including 10 noncom-

mercial educational stations operating in a frequency band set aside for that purpose.

Not until late 1945 and 1946 after wartime limitations were removed, did FM's development as a broadcasting medium begin to realize in fact the promise that was held out for it in its earlier years. By Oct. 1946, a year after the FCC resumed its normal licensing procedures, 540 FM stations were authorized outright or conditionally. Approximately 100 were on the air at the end of 1946, and scores of others were preparing to commence operations early in 1947. That no more were actually in operation was attributed to early postwar lags in production, brought on by strikes and shortages of vital equipment parts, which limited the output of both station equipment and FM receiving sets.

A great majority of the FM grants went to licensees of AM stations. An analysis of the 504 issued to Oct. 1946 showed 403, or 74.6%, were held by persons or companies already in the AM field.

A total of 204, or 37.8%, were in the hands of newspaper publishers.

In comparison to the 10 noncommercial educational FM stations authorized as of early 1945, 6 were on the air and 21 were under construction in late 1946, while 23 applications were pending before the FCC.

In several states the applications were more or less integrated into proposed state-wide plans for noncommercial educational stations.

While initial experiments in FM broadcasting included operations around 30 megacycles (mc.) as well as in the higher frequencies, the 1940 allocation for commercial operation assigned FM a band of frequencies in the 50-mc. region. In 1945 the band was reallocated to the portion of the spectrum between 88 and 108 mc., and despite the objections of some FM pioneers, including the inventor of the system, FCC authorities insisted that it would remain "upstairs" and told manufacturers they could proceed on that basis.

From its earliest days, FM advocates predicted the new form of broadcasting would permit a doubling or tripling of the number of engineeringly operable broadcasting stations. The FCC shared this view, anticipating that it eventually would replace AM stations altogether, with the possible exception of a few high-power AM outlets to provide service to wide stretches of underserved areas where operation of a number of stations, either AM or FM, would be economically impractical.

In line with this outlook for FM, the Columbia Broadcasting system, in the course of the 1946 clear-channel hearings conducted by the FCC, proposed a system of nationwide FM networks which it contended would provide better and more nearly complete service to the nation than would be possible through a rearrangement of AM stations.

Despite the progress in the FM station field, FM remained comparatively unheard even in the latter part of the decade 1937-46. In 1941 it was estimated that approximately 500,000 sets, representing a \$30,000,000 investment by listeners, were in use in the United States.

Production of FM receiver sets did not reach substantial quantity until the latter part of 1946; total output for that year was estimated to be slightly under 200,000.

Those who did have FM sets heard much the same type of programming which they were accustomed to hear on AM. FM stations owned by AM licensees engaged, for the most part, in duplication of their programs over both stations, within limitations imposed by the American Federa-

Upper left: Autograph hunters swamping Bob Hope with requests during an evening broadcast. Hope's program was rated the most popular on the U.S. networks in 1944 and 1945, according to C. E. Hooper Inc.

Lower right: Mark Warnow and his dance orchestra rehearsing a musical number for "The Hit Parade." Popular music accounted for a little more than 10% of U.S. evening network programs in 1946

tion of Musicians' (A.F.M.) ban on duplication of music played by A.F.M. musicians except upon payment of a "stand-by" fee. Independent FM stations generally followed AM programming lines with emphasis on music, which best displayed the clarity and high fidelity of FM.

The FCC's original rules for commercial FM operations required stations to broadcast at least two hours of unduplicated programs a day, but this requirement was waived in 1945 and the commission reiterated in 1946 that it did not intend to reinstate the rule in the immediate future.

Although United States broadcasters pioneered in FM, other countries throughout the world adopted it. In 1946 FM stations were in operation in Australia, South America, South Africa, Europe and Canada, and in Great Britain the British Broadcasting Corp. announced its intentions of establishing an FM network in the British Isles.

Facsimile.—This method of record transmission by radio, similar to wirephoto or radiophoto, remained in an "experimental" status throughout the decade. Great technical strides were made, however, and vast expansion was predicted for the postwar period. Some leaders in this field predicted home facsimile sets would be in operation in some 12 cities of the United States in 1947.

From prewar transmissions of about 4 sq.in. of copy per minute, facsimile operations progressed to 28 and later to 45 sq.in. per minute, with laboratory speeds up to 88 sq.in. reported in late 1946. The transmissions were in sufficient detail to handle all kinds of type and illustrations.

Pioneers in this new art, which was used with great success on the battlefields, considered it a natural adjunct of newspapers, not competition for them. It was generally agreed, however, that more experimentation was needed to determine the exact types of service the public would find most desirable. Leaders generally felt that the initial service, from the standpoint of transmissions for home receivers, probably would include radio program logs, retail advertising, news bulletins, stock reports, quotations, scores of athletic events, pictures and similar material which would extend the continuity of service between newspaper editions.

Facsimile functions on a narrow band (two kilocycles) and can be multiplexed on FM channels without disturbing the FM transmission. Broadcasts of this type can be received at any point where sound programs from the same station can be heard.

Stratovision.—A major innovation was the plan announced in 1945 by Westinghouse Electric and Manufacturing Corp., by which airborne transmitters would relay television, FM and other broadcast services by interlacing transmission from plane to plane, flying anchored courses at 30,000 feet.

The system was devised by Charles E. Nobles, 27-year-old radar expert employed by Westinghouse, whose engineers estimated that Stratovision could provide coverage of a 211-mi. area with one-fiftieth of the amount of power required by a 50-kilowatt transmitter on the ground to cover a 100-mi. radius. Its developers also considered it an ideal medium for bringing high-definition television (both black-and-white and colour) into reality. Tests were conducted throughout 1946 by Westinghouse in co-operation with Glenn L. Martin Co., co-developers of the system.

Subscription Radio.—Another innovation of the decade was subscription radio, a plan for a nonadvertising FM broadcast service in which the subscriber would pay a regu-

lar rental fee for program service. Founded and headed by William Benton, then chairman of Muzak corporation, vice-president of the University of Chicago and chairman of Encyclopædia Britannica, Inc., subscription radio proposed to offer subscribers an FM service over three channels. One channel would provide serious music, one popular music and one diversified program fare. It was popularly called "pig squeal" because only subscribers would have a special patented attachment to permit tuning to the three subscription radio channels; nonsubscribers would hear a high-frequency heterodyne described as a "pig squeal."

Details of the plan were presented at the FCC spectrum allocations hearings in 1944, with established broadcasters and manufacturers opposing it on the ground that it was antiadvertising and anticommercial radio. Benton announced suspension of the project in Sept. 1945, coincident with his assumption of office as assistant secretary of state, explaining that his government position conflicted with the private venture.

Manufacturing and Selling

The output of radio receiving sets by United States manufacturers experienced a gain of approximately 85.5% between 1937 and 1946 despite labour strife, parts shortages and other drawbacks which slowed production lines during much of the latter year. As 1946 ended, the Radio Manufacturers' association (R.M.A.), composed of most of the major manufacturing companies, estimated the year's volume at 15,000,000 sets as compared with 8,083,144 in 1937.

Sales lagged slightly behind production throughout the prewar years. After U.S. entry into World War II, however, when there was no production for civilian use, the demand for new and replacement sets mounted to such a peak that a quick market was assured for virtually every receiver turned out in late 1945 and all of 1946.

Table IX shows progress made in production, retail sales, and retail value of sets sold from 1937 through 1946. Production figures were supplied by R.M.A. and represented the output of its member companies. The columns on retail sales and sales values from 1937 through 1945 were taken from a compilation prepared for the 1946 *Broadcasting Yearbook* by O. H. Caldwell, editor of *Television and Retailing*.

Table IX.—U.S. Civilian Set Production and Sales*
1937-46, inclusive

Year	Sets Produced	Retail Sales	Retail Value
1937	8,083,144	8,064,780	\$450,000,000
1938	7,141,811	6,000,000	\$210,000,000
1939	10,762,631	10,500,000	\$354,000,000
1940	11,831,187	11,800,000	\$450,000,000
1941	13,642,334	13,000,000	\$460,000,000
1942	4,306,983†	4,400,000	\$154,000,000
1943	700,000‡	\$24,000,000
1944
1945§	500,000	\$20,000,000
1946 	15,000,000	15,000,000	\$750,000,000

*Value of tubes in receivers is included in figures on retail cost.

†Civilian production was terminated April 22, 1942.

‡Sales include 350,000 new and 350,000 used receivers.

§Reconversion to civilian production was undertaken at full scale after V-J day, but shortages of vital materials and other difficulties limited the year's output to approximately 300,000 new receivers.

|| Figures for 1946 are estimates.

Tube Production and Sales.—With the same temporary lags that were evident in set production, first during the general business recession of 1938 and later when military needs commanded virtually the entire energy of the radio manufacturing industry, radio tube production ranged upward from 92,055,700 tubes in 1937 to 159,120,562 during the first 10 months of 1946, according to R.M.A. reports.

In normal times, replacement tubes had represented from 25% to 40% of total tube production, but difficulty in securing replacements during World War II created an abnormal demand for them when they returned to the market in 1945 and 1946. In Dec. 1946, however, R.M.A. reported that tubes would be available in ample supply in the first quarter of 1947.

Year-by-year trends in production, sales and retail sales values of tubes are shown in Table X, comparable to the preceding table on sets and based on the same sources of information:

Table X.—U.S. Civilian Tube Production and Sales
1937-46, inclusive

Year	Tubes Produced	Retail Sales	Retail Value
1937	92,055,700	91,000,000	\$85,000,000
1938	74,690,527	75,000,000	\$93,000,000
1939	98,499,926	91,000,000	\$114,000,000
1940	106,850,747	115,000,000	\$115,000,000
1941	108,451,993	130,000,000	\$143,000,000
1942	114,238,098	87,700,000	\$94,000,000
1943	17,000,000	\$19,000,000
1944	22,000,000	\$25,000,000
1945	30,000,000	\$35,000,000
1946	159,120,562*	159,120,562†	\$186,150,000†

*Production, January-October.

†Estimated, January-October, on basis of strong demand for replacement tubes and also for new sets, whose tubes were counted in total production.

Automobile Radios.—The manufacture of receivers for automobile use made substantially less gain during the decade than did the output of other sets and tubes. Even in its best year in history, 1941, this phase of the industry recorded less than a 15% increase in units over its previous high mark, reached in 1937. Primarily because the public demand was centred on new console and table-model receivers for home and office use, manufacturers as a whole devoted only slight attention to automobile sets after World War II ended.

Statistics prepared and copyrighted by Caldwell-Clements, Inc., publishers, showed 1,750,000 automobile radios produced in 1937 and put their retail value at \$87,500,000. The following year, production dropped to 800,000 sets with a retail value of \$32,000,000. In 1939 it rose to 1,200,000 (retail value \$48,000,000), and in 1940 to 1,700,000 (\$60,000,000). The total reached 2,000,000 in 1941, but lower prices then in effect left their retail value some \$17,500,000 less than the value of the 1,750,000 sets of 1937. In 1942 production dropped to 350,000 receivers valued at \$12,250,000, while the 1946 total, after 3 years of nonproduction, was reported at 150,000 sets worth \$9,000,000 at retail.

Wartime Production.—The manufacturing industry reached an all-time peak in volume of production during World War II, almost all of it in the war category. Within months after the War Production board froze the manufacture of all types of radio receivers on April 27, 1942, the industry was turning out \$30,000,000 worth of military products monthly. The next year the average reached \$250,000,000 monthly. It kept that pace, or exceeded it, throughout World War II. In both 1944 and 1945 the industry's total output was estimated at \$5,000,000,000 or more annually, and in 1944 radio-radar production alone accounted for approximately \$3,000,000,000 of the year's total.

In 1943 when the radio manufacturing industry hit its wartime stride, its total investment was estimated at \$350,000,000, its employees numbered 400,000, its annual pay roll was \$900,000,000 and its annual gross revenue was reported as \$3,500,000,000. Investment remained static from 1943 through 1945, but gross revenues, employment and pay roll reached their peaks in 1944: \$4,750,000,000

revenues, 530,000 employees and a \$1,200,000,000 pay roll. With cutbacks following the end of World War II, 1945 gross revenue totalled about \$3,000,000,000, approximately 350,000 employees were retained and payroll was \$750,000,000. These figures cover approximately 1,200 manufacturers of all types of radio-electronic goods.

By way of comparison, the 1946 figures for 1,100 radio manufacturers were reported by Caldwell-Clements, Inc. and its *Tele-Tech* magazine as follows: Total investment \$60,000,000; annual gross revenue \$350,000,000; employees, 80,000; annual pay roll, \$90,000,000.

Throughout World War II, radio distributors, dealers and similar establishments represented a total investment of approximately \$280,000,000 and reported annual gross revenues of around \$200,000,000. Their employees numbered about 100,000 and their annual pay roll was \$150,000,000. When sets became available once more, rapid expansion was evident in this field. In 1946 according to the Caldwell-Clements' reports, their total investment reached \$300,000,000; gross revenues climbed to \$700,000,000; employees totalled 125,000 and the annual pay roll was \$200,000,000.

Regulations

Regulation by government in virtually all parts of the world moved toward a closer check on broadcasting activities, although in the United States radio still remained a privately owned, free enterprise without competition from the government. In many countries, during the decade 1937-46, two systems of broadcasting arose—one owned and operated by the government, the other by private enterprise.

General regulations on a world-wide basis were drafted by the various world and regional broadcasting and telecommunications conferences (see *World Conferences*, page 713). Each country, however, promulgated its own regulatory measures.

As the decade closed, various Latin American nations had organized to fight government encroachment into free radio. They called upon the broadcasters of the United States to lend moral and financial support in their announced intention of keeping radio on a free, competitive basis. As a result of their concerted efforts, broadcasters of North, South and Central America met in Mexico City in late Sept. 1946 and organized the Inter-American Broadcasting association. At the close of the year, the National Association of Broadcasters of the United States had not formally determined to participate as a member, although sentiment favoured it.

In England the British Broadcasting corporation's charter was renewed until 1951, which meant the end of any hopes that Britain might permit commercial broadcasting patterned after the United States. France, which enjoyed both a government and private system of broadcasting prior to World War II, was operating only its government radio.

In Canada, where the government-owned Canadian Broadcasting corporation continued to compete with the private Canadian Association of Broadcasters, heated debates featured sessions of parliament in 1946, as the government proposed to take three clear channels from privately owned radio stations for government-operated stations.

Federal regulation of radio in the United States resulted in several supreme court decisions, some of which interpreted the Communications act of 1934 as giving the FCC broad powers over the broadcasting industry. Among the major court decisions and government regulations of the

decade ending with 1946 the following were, perhaps, the most significant: (1) The power of radio stations in the United States was limited to 50,000 watts; (2) Antimonopoly regulations affecting the networks were upheld by the supreme court; (3) ownership of more than one station serving the same area was forbidden; (4) the FCC proposed to prohibit newspapers from owning radio stations but after more than two years of investigation dropped the proceedings and announced that each application would be decided on its merits; (5) licences of radio stations in the U.S. were extended step by step from six months to the maximum three-year limit allowed by law; (6) commercial operation of frequency modulation (FM) and television was authorized by the FCC; (7) a reallocation of frequencies resulted in moving FM from 42,000–50,000 kc. to 88,000–108,000 kc.; (8) the FCC issued a warning in a report called the "Blue Book" to radio stations that it was displeased with "excessive commercialism"; (9) the supreme court ruled that the FCC could not consider financial injury to a rival established station in granting new applications if frequencies were available; at the same time the court held that the FCC had no control over business practices of radio stations.

The foregoing might be termed the major regulatory developments of the decade in the U.S., but many others marked the ten-year period. These dealt with political broadcasts, identification of commercial sponsors, the rights of atheists to time on the air and the requirement by the FCC of detailed financial and employment data from radio stations.

Chain Broadcasting Regulations.—Perhaps the most important and far-reaching regulations of the decade were those known as the Chain Broadcasting Regulations or "network monopoly rules." They affected the majority of radio stations in the United States. While the FCC had no jurisdiction over the networks, except as licensees of radio stations owned by the chains, the regulations actually controlled network contracts inasmuch as licensees dealing with networks were controlled.

Hearings on the proposed network regulations began before a subcommittee of the FCC on Nov. 14, 1938, and terminated on May 19, 1939. The FCC proposed to license networks as well as broadcasting stations, do away with exclusive network contracts and reduce the length of network contracts with affiliate stations from five years to one year.

For two years after the hearings closed, there was considerable talk in the radio industry about the proposed network regulations, but the commission took no action until May 2, 1941, when—at a secret meeting—a group of eight stringent regulations was adopted. In substance these proposed rules provided that: (1) No licence would be granted to a radio station which had an exclusive contract with any network; (2) no licence would be granted to any station which had a contract which prevented other stations in the same area or other areas from carrying network programs not broadcast by the first station; (3) network affiliate contracts were limited to one year; (4) networks could not hold optional time on an affiliate station; (5) stations were free to reject any network program, regardless of agreements with the network; (6) no licence would be granted to a network-owned station in an area where the network already had a station, and no licence would be granted to a network in an area where competition was not possible; (7) no licence would be granted to a station having a contract with a network which operated more than one network; (8) no networks could fix rates of station affiliates.

On the following June 2 the senate Interstate Commerce committee, under Chairman Burton K. Wheeler, Democrat of Montana, began an investigation of the proposed regulations. An interested member of the committee, who attended most of the sessions, was the senator from Missouri, Harry S. Truman.

Following the senate inquiry the FCC on July 21, 1941, postponed the effective date of the network regulations to Sept. 16, then on Aug. 28 the FCC announced an indefinite postponement. On Oct. 11, 1941, the commission announced amendments to the regulations, to become effective on Nov. 15. CBS and NBC filed suit in the federal district court, southern district of New York, to restrain the FCC from enforcing the network regulations.

The supreme court, however, on May 10, 1943, handed down an opinion sustaining the regulations and holding that the congress gave the commission "broad powers" over radio broadcasting. It was that decision, which was split 5–2, that led to demands on the part of the radio industry for new radio legislation. The supreme court held, in the opinion written by Justice Felix Frankfurter, in part:

"The Act itself establishes that the Commission's powers are not limited to the engineering and technical aspects of regulations of radio communication. Yet we are asked to regard the Commission as a kind of a traffic officer, policing the wave lengths to prevent stations from interfering with each other. But the Act does not restrict the Commission merely to supervision of the traffic. It puts upon the Commission the burden of determining the composition of that traffic. The facilities of radio are not large enough to accommodate all who wish to use them. Methods must be devised for choosing from among the many who apply. And since Congress itself could not do this, it committed the task to the Commission."

Following the supreme court decision the network regulations became effective on June 14, 1943. They were as follows:

Exclusive affiliation of station.—No licence shall be granted to a standard broadcast station having any contract, arrangement, or understanding, express or implied, with a network organization under which the station is prevented or hindered from, or penalized for, broadcasting the programs of any other network organization.

Territorial exclusivity.—No licence shall be granted to a standard broadcast station having any contract, arrangement, or understanding, express or implied, with a network organization which prevents or hinders another station serving substantially the same area from broadcasting the network's programs not taken by the former station, or which prevents or hinders another station serving substantially a different area from broadcasting any program of the network organization. This regulation shall not be construed to prohibit any contract, arrangement, or understanding between a station and a network organization pursuant to which the station is granted the first call in its primary service area upon the programs of the network organization.

Term of affiliation.—No licence shall be granted to a standard broadcast station having any contract, arrangement, or understanding, express or implied, with a network organization which provides, by original term, provisions for renewal, or otherwise for the affiliation of the station with the network organization for a period longer than two years: *Provided*, that a contract, arrangement, or understanding for a period up to two years, may be entered into within six months prior to the commencement of such period.

Option time.—No licence shall be granted to a standard broadcast station which options for network programs any time subject to call on less than 56 days' notice, or more time than a total of 3 hours within each of 4 segments of the broadcast day, as herein described. The broadcast day is divided into 4 segments, as follows: 8:00 A.M. to 1:00 P.M.; 1:00 P.M. to 6:00 P.M.; 6:00 P.M. to 11:00 P.M.; 11:00 P.M. to 8:00 A.M. Such options may not be exclusive as against other net-

work organizations and may not prevent or hinder the station from optioning or selling any or all of the time covered by the option, or other time, to other network organizations.

Right to reject programs.—No licence shall be granted to a standard broadcast station having any contract, arrangement, or understanding, express or implied, with a network organization which (a), with respect to programs offered pursuant to an affiliation contract, prevents or hinders the station from rejecting or refusing network programs which the station reasonably believes to be unsatisfactory or unsuitable; or which (b), with respect to network programs so offered or already contracted for, prevents the station from rejecting or refusing any program which, in its opinion, is contrary to the public interest, or from substituting a program of outstanding local or national importance.

Network ownership of stations.—No licence shall be granted to a network organization or to any person directly or indirectly controlled by or under common control with a network organization, for more than one standard broadcast station where one of the stations covers substantially the service area of the other station, or for any standard broadcast station in any locality where the existing standard broadcast stations are so few or of such unequal desirability (in terms of coverage, power, frequency, or other related matters) that competition would be substantially restrained by such licensing.

Dual network operation.—No licence shall be issued to a standard broadcast station affiliated with a network organization which maintains more than one network: *Provided*, that this regulation shall not be applicable if such networks are not operated simultaneously, or if there is no substantial overlap in the territory served by the group of stations comprising each such network.

Control by networks of station rates.—No licence shall be granted to a standard broadcast station having any contract, arrangement, or understanding, express or implied, with a network organization under which the station is prevented or hindered from, or penalized for, fixing or altering its rates for the sale of broadcast time for other than the network's programs.

New Rules.—Throughout the decade, the Federal Communications commission adopted new rules and regulations at intervals, but perhaps none were so far-reaching as those placed into effect on Aug. 1, 1939, governing standard broadcasting. These regulatory measures, the first major ones of the ten-year period, among other things limited the power of radio stations in the United States to 50,000 watts, although stations of greater power were operating in Mexico. WLW, Cincinnati, O., one of the pioneer broadcasting stations of the nation, had been operating from May 1, 1934, until March 1, 1939, with 500,000 watts by special authorization of the commission.

The senate on June 6, 1938, adopted a resolution introduced by Sen. Burton K. Wheeler to the effect that it was the "sense of congress" that powers in excess of 50 kw. would not serve the public interest. Senator Wheeler expressed fears that a "dozen superpowered stations placed strategically throughout the nation would create a monopoly and force the little fellow out of business."

But among the high points of the 1939 regulations was the designation of 26 channels as class I-A clear channels, on which 50-kw. stations would operate without nighttime interference. Broadcasting stations operating on the clear channels with high power are heard at great distances through sky wave signals. That is, the signals at night are reflected back to earth over a wide area from the ionosphere. Duplicate daytime operation on the same channel is possible if the stations are separated by sufficient distance. In the U.S. the distance was determined as approximately 750 mi.

In addition to the 26 class I-A channels, the commission also set aside an additional 18 channels for class I-B operation. That is with some duplication at night but requiring the secondary stations to protect the dominant sta-

tion by using directive antennas and lower power.

To encourage broadcasters to make full use of their facilities, the commission announced it would grant station power increases where such increases were needed and feasible. In allocating the 26 class I-A channels and 18 class I-B channels, the FCC said it wanted to ensure as much rural coverage as possible. Less than six years later, however, the FCC reopened the clear-channel question by announcing, on Feb. 21, 1945, that public hearings would be held to determine what changes, if any, should be made in policies affecting clear-channel stations. The commission said a re-examination of the clear-channel question "is necessary since the Commission studies reveal there are still large areas within the United States which receive no radio service at all during the daytime hours and no primary service at night." Hearings, called for May 9, 1945, but subsequently postponed several times until Jan. 14, 1946, were designated for the purpose of determining:

1. What recommendation concerning the matters covered by this order the Commission should make to the Dept. of State for changes in provisions of the North American Regional Broadcasting Agreement.
2. Whether the number of clear channels should be increased or decreased and what frequencies in the standard broadcast band should be designated as I-A channels and as I-B channels.
3. What minimum power and what maximum power should be required or authorized for operation on clear channels.
4. Whether and to what extent the authorization of power for clear channel stations in excess of 50,000 watts would unfavourably affect the economic ability of other stations to operate in the public interest.
5. Whether the existing geographical distribution of clear channel stations and the areas they served represented an optimum distribution of radio service among the several states and communities specified in Sec. 308(b) of the Communications Act required a geographical redistribution.
6. Whether it was economically feasible to relocate clear channel stations so as to serve those areas which did not receive service.
7. What new rules or regulations, if any, should be promulgated to govern the power or hours of operation of class II stations operating on clear channels.
8. What changes the Commission should order with respect to geographical location, frequency, authorized power or hours of operation of any licensed clear channel station.
9. Whether and to what extent the clear channel stations rendered a program service particularly suited to the needs of listeners in rural areas.
10. The extent to which the service areas of clear channel stations overlapped and the extent to which this involved a duplication of program service.
11. What recommendation, if any, the Commission should make to the Congress for the enactment of additional legislation on the matters covered by this order.

Although the FCC set out to determine what recommendations should be made to the state department with reference to the North American Regional Broadcasting agreement, the Second North American Regional Broadcasting conference was held, and an interim agreement was adopted on Feb. 25, 1946, before the clear-channel hearings had barely gotten under way (see *World Conferences*, page 713).

Hearings were held sporadically throughout 1946 on the clear-channel question. American radio industry was clearly divided into two schools of thought. Proponents of clear-channel stations urged that the commission permit powers in excess of 50 kw. and restrict the number of secondary stations on clear channels. This view was represented by the Clear Channel Broadcasting service (C.C.B.S.), an organization composed of clear-channel broadcasters. Only through increased power and exclusive use of the clear channels could the remote rural areas be reached, the C.C.B.S. argued.

On the other hand, broadcasters owning smaller stations and represented by the Regional Broadcasting com-

mittee, told the FCC that rural coverage could be assured only if clear channels were broken down to permit more than one station to operate on each channel.

In the meantime, the commission began granting construction permits for daytime stations on class I-A channels and adding more stations to the class I-B channels. A group of clear-channel broadcasters petitioned the FCC to stop granting daytime stations on clear channels until after the hearings were ended and the issue resolved. They contended that should the commission eventually permit power in excess of 50,000 watts, a serious interference problem would arise. That petition was denied.

Clear-channel broadcasters used Mexico as an example of competition from outside the U.S. Several broadcasting stations in Mexico had been using 100,000 watts power for some years. In 1945 Emilio Azcarraga, Mexico's foremost broadcaster and operator of XEW in Mexico City, announced plans to build a station using 1,000,000 watts power.

Multiple Ownership.—Following several months of investigation, the FCC on Aug. 5, 1941, announced adoption of a proposed order banning multiple ownership of standard broadcast stations. Under its proposal, the FCC would require some 40 licensees to dispose of 1 or more stations serving areas similar to other stations owned by the same licensee. Oral argument was held on Oct. 6 that year, but no further announcement was made until Nov. 23, 1943, when the commission, in a public notice, announced it had adopted a new regulation, banning multiple ownership. The regulation, which became effective June 1, 1944, follows:

No licence shall be granted for a standard broadcast station, directly or indirectly owned, operated or controlled by any person where such station renders or will render primary service to a substantial portion of the primary service area of another standard broadcast station, directly or indirectly owned, operated or controlled by such person, except upon a showing that public interest, convenience and necessity would be served through such multiple ownership situation.

Newspaper Ownership.—By a vote of 3-2, the Federal Communications commission on March 19, 1941, adopted an order calling for an investigation into ownership of radio stations by newspapers. "Hearings will be conducted to determine whether or not joint control of newspapers and radio broadcasting stations tends to result in an impairment of radio service under the standard of 'public interest, convenience and necessity,'" said the FCC public notice announcing the inquiry.

A supplemental order was issued in July 1941 broadening the scope of the investigation. Among the new issues was this: "To determine whether joint operation of newspapers and broadcast stations tends or may tend to prejudice the free and fair presentation of public issues and information over the air, or to cause editorial bias or distortion, or to inject editorial policy or attitude into the public service rendered by broadcast stations as a medium of public communications."

Just prior to the first order of March 16, the U.S. court of appeals for the District of Columbia, in an appeal of the *El Paso Times* (Tex.), which sought a radio station, held: "We know of no provision of statute or rule of law and are cited to none, which forbids broadcasting by the ownership of a newspaper."

Hearings began in mid-July 1943, and continued for more than six months. The American Society of Newspaper Editors bitterly opposed the commission, contending that under the Communications act the FCC had no authority to inquire into newspaper ownership of radio stations. In Jan. 1942 the U.S. court of appeals for the

District of Columbia, holding that the FCC was empowered to issue subpoenas for any investigation it deemed necessary "in the public interest," declared that there was nothing in the Communications act to discriminate against newspaper ownership of broadcasting stations.

Meanwhile, the commission ordered placed in the pending files all applications of newspapers for radio stations. A short time after that order, however, the wartime construction freezes were issued, and radio construction generally was at a standstill.

Finally, on Jan. 13, 1944, the FCC dismissed the newspaper-ownership proceedings and announced that all applications for broadcast licences would be determined on the individual merits of each. However the commission left itself some leeway in connection with applications of newspapers, when it said:

"In the processing of individual applications for licenses, the Commission will inquire into and in its decision give expression to 'public interest' considerations. The Commission does not feel that it should deny a license merely because the applicant is engaged or interested in a, particular type of business. However, it does not intend in granting licenses in the public interest to permit concentration of control in the hands of the few to the exclusion of the many who may be equally well qualified to render such public service as is required of a licensee."

In decisions following the newspaper-ownership dismissal, the commission denied some newspapers applications when competitive applicants not in the publishing field were bidding for comparable facilities. This was true in communities with one newspaper and no radio stations. On the other hand, the FCC granted new stations to some newspapers, while denying applications of others.

Other Regulations.—Many other regulatory measures were placed into effect by the FCC during the ten-year period, as follows:

The commission on Oct. 18, 1937, set aside channels in the ultra-high frequency band above 30,000 kc. for television.

Redefining its rules governing candidates for political office and their use of time on radio stations, the commission said a "legally qualified candidate means any person who has publicly announced that he is a candidate" for nomination or public office. That was on Nov. 26, 1941. Three years later, on Dec. 13, 1944, the FCC adopted new rules governing political broadcasts, which required radio stations to state properly the "true source of payment" for political broadcasts. This rule followed an investigation by the senate campaign expenditures committee which charged that certain political candidates paid for broadcast time of speakers, although radio stations made no mention that the programs were paid for.

Licences of radio stations in the U.S. were extended on Dec. 15, 1943, from two to three years, the maximum under the Communications act.

On July 25, 1944, the FCC asked congress for authority to pass on the prices of radio stations which were being sold. The commission listed sale prices of several, ranging from \$500,000 paid for WINX, in Washington, D.C., a 250-watt local station, by Eugene Meyer, Jr. & Co. Meyer was publisher of the *Washington Post*. The \$987,000 for the 10,000-watt WQXR in New York, paid by the *New York Times*, also was set out by the FCC as an example of high prices.

Subsequently the commission on July 18, 1946, adopted a rule requiring that when stations were placed on sale

the owners must advertise for 60 days in local newspapers to permit competitive bidders. The commission then would determine which of the bidders should buy the station. Several announced sales were withdrawn after the FCC invoked its rule.

In Aug. 1946 the backlog of applications was so great at the FCC that four "processing lines" were set up to handle them in the order of their respective filings. A total of 859 pending applications were being disposed of in the mass production system as the year closed.

Reallocation of Frequencies.—To the new static-free service, frequency modulation (FM) and to television, the reallocation of frequencies from 25,000 to 30,000,000 kc. opened the way for wide development. FM had been operating in the band from 42–50 megacycles (mc.). The commission proposed to move it upward in the radio spectrum.

Six weeks of general allocation hearings were held in late 1944, during which time Dr. Kenneth A. Norton, an engineer with the Army signal corps (formerly with the FCC and the U.S. bureau of standards) testified that under his calculations FM would give a better service in the frequencies around 100 mc.

Industry engineers opposed him. They contended there was no quantitative data to bear out Norton's contentions. Leading the opposition was Maj. Edwin Howard Armstrong, professor of electrical engineering at Columbia university, New York, and inventor of frequency-modulation broadcasting.

But despite the industry opposition and in the face of threats of congressional investigation, the FCC on May 25, 1945, issued its final allocation, giving FM 100 channels (each 200 kc. wide) in the spectrum between 88 and 108 mc. Hearings subsequently were reopened on petition of the Zenith Radio Corp., which sought to have a portion of the 42–50 mc. band allocated also to FM. In congress, Rep. William Lemke, Republican of North Dakota, introduced a bill to require the FCC to allocate FM in the 50-mc. region.

The commission subsequently denied the Zenith petition, and Lemke's bill died in committee when the 79th congress expired.

Blue Book.—On March 7, 1946, the FCC issued a lengthy report entitled "Public Service Responsibility of Broadcast Licensees." This document, known as the *Blue Book*, became radio's most controversial issue as between the regulatory federal agency and the broadcasting industry. The *Blue Book* criticized radio generally, accused it of being "over-commercial" and of not broadcasting a sufficient number of "sustaining public interest programs."

Eleven months before the report was issued, the FCC placed on temporary licence a half dozen broadcasting stations. At the time the commission announced it was investigating program logs of several stations to determine whether they were broadcasting in keeping with promises made when their respective applications were filed.

In the *Blue Book*, the FCC said that in future considerations for licence renewals the FCC would give "particular consideration" to four program-service categories which it considered relevant to the "public interest," as follows:

- (1) The carrying of sustaining programs, including network sustaining programs, with particular reference to the retention by licensees of a proper discretion and responsibility for maintaining a well-balanced program structure;
- (2) The carrying of local live programs;
- (3) The carrying of programs devoted to the discussion of public issues;

- (4) The elimination of advertising excesses.

The commission accused five broadcasting stations of "over-commercialism" and of failing to operate their stations according to promises made in applications—some dating back to 1932. Among these stations was WBAL, Baltimore, Md., a 50,000-watt clear-channel station owned by Hearst Radio Inc., subsidiary of William Randolph Hearst's newspaper enterprises.

At the close of 1946 it appeared that the WBAL case would reach the supreme court. In mid-Dec. 1946 Hearst attorneys filed with the commission a petition charging that the FCC staff which compiled the *Blue Book* had made "false, distorting and misleading" references to the Hearst station. The petition demanded "an appropriate retraction of the (*Blue Book's*) unfair accusation against the operation" of WBAL by Hearst Radio, and for "appropriate action" by the FCC "with respect to the person or persons responsible."

The FCC had designated the Hearst licence-renewal application for hearing, after keeping the station on temporary licence, from mid-April 1945. Pres. Justin Miller of the National Association of Broadcasters had assailed the *Blue Book* and the commission since its issuance. He resigned from the U.S. court of appeals for the District of Columbia in Oct. 1945, to accept the presidency of the N.A.B. Miller, who had written several radio opinions as a member of the appellate court, in speeches throughout the United States declared the Communications act expressly forbade the FCC from having anything to do with programs or business practices of broadcast stations.

Court Decisions.—The supreme court, during the decade 1937–46, handed down several interpretations of the Communications act of 1934, as amended.

On March 6, 1940, the high tribunal held that the FCC could not consider economic injury to an existing station in granting a licence to a competitive applicant. That decision held that the commission had no control over the business practices or economics of broadcast stations. On April 6, 1942, the court upheld the right of the U.S. court of appeals for the District of Columbia, to issue stay orders against FCC actions.

On Dec. 3, 1945, the court ruled that the FCC must hold hearings before making decisions in cases where mutually exclusive applications were involved. The FCC had granted one station a licence without a hearing while designating for hearing an application for the same wave length in a near-by community.

On Dec. 9, 1946, the supreme court held that the FCC was empowered to revoke a radio station licence where falsification was involved. The court upheld the commission's action of a year before refusing to renew the licence of WOKO, Albany, N.Y., because a 24% beneficial interest held by Sam Pickard, one-time federal radio commissioner, was not reported to the commission until after the FCC began an investigation some 12 years later.

Performers' Rights

Performing artists as well as composers of musical compositions learned, through court decisions in the United States, that they could protect their own works. The decade 1937–46 found composers of drama and music organized to protect their individual and collective rights.

On a world-wide basis, the Confédération Internationale des Sociétés d'Auteurs et Compositeurs, created in 1926 with headquarters in Paris, had enlarged its scope of operations by 1937 to include musical copyright organizations of many countries. It was the outgrowth of the French Society of Dramatic Authors and Composers.

Annual congresses, held in various European cities, ended with a 1938 meeting in Stockholm. With the advent of World War II, the confederation became somewhat inactive, but in March 1946 the first postwar meeting was held in Paris. By agreement the next international convention was scheduled in Washington, D.C., Oct. 21-26, 1946. It was held in the Library of Congress.

The American Society of Composers, Authors and Publishers (A.S.C.A.P.), which had been the largest music licensing organization in the U.S., became a member of the confederation, and was host to the world meeting in Washington, D.C., in 1946.

As 1937 began, radio stations in the U.S. were faced with paying a sustaining fee plus 5% of their gross receipts if they continued to use music on which A.S.C.A.P. held the copyright. With fees for broadcasting music rising at a rapid rate, the National Association of Broadcasters undertook a study. A bureau of copyrights, meantime, had been established by the N.A.B. to advise broadcasting stations on the use of music. Several U.S. stations were threatened with suits if certain musical compositions, owned by A.S.C.A.P. members, were played without paying additional fees. As a result of the monopoly, the N.A.B. board of directors on April 1, 1937, authorized the creation of the radio industry's own music copyright bureau. By early 1940 it was functioning as Broadcast Music, Inc., with a \$1,250,000 fund supplied by the major networks and independent stations of the country. A permanent organization was formally approved at the 1939 N.A.B. convention in San Francisco the following August.

A.S.C.A.P. early in 1940 proposed new contracts for stations and networks, boosting its royalties from an estimated \$4,500,000 to \$9,000,000 annually. Radio stations refused to sign. On May 10, 1940, the department of justice instituted criminal action against A.S.C.A.P. for alleged violation of the Sherman Anti-Trust law. The following December, Attorney General Robert H. Jackson filed new criminal antitrust suits against A.S.C.A.P., B.M.I., NBC and CBS, as a result of the music controversy. By 1941 radio stations throughout the U.S. were allowing their A.S.C.A.P. contracts to expire and were broadcasting B.M.I. music. A.S.C.A.P. members and officials felt that the impact would result in public reaction, but the millions of radio listeners in the United States apparently were unperturbed. The expected protests did not materialize.

On Jan. 31, 1941, B.M.I. signed a consent decree to cease and desist from price fixing or any other purported violations of antitrust laws, to become effective when A.S.C.A.P. signed a similar decree. A.S.C.A.P. subsequently signed, but not before a federal court found the organization guilty of criminal violation and fined it \$35,250.

Prior to the N.A.B. convention in the spring of 1941, Mutual Broadcasting system signed a new contract with A.S.C.A.P., breaking the deadlock between stations and networks and the copyright organization. The figure was 3% of its receipts for musical programs. Later in the year, NBC and CBS signed at 2¾% and A.S.C.A.P. lowered Mutual's fee. A.S.C.A.P. offered its music to independent stations at 2½%.

With a \$1,000,000 annual budget, B.M.I. approved long-term contracts at a 25% reduction to radio stations. With competition between two major copyright organizations, fees came down and the radio industry had a wide selection of music as the decade closed.

The decade saw two opposite court decisions involving the right of radio stations to broadcast recorded music of performing artists. On Oct. 8, 1937, the Pennsylvania supreme court held that performing artists had a property

right in their recorded performances of musical compositions and therefore radio stations had to obtain permission from the artists before using their records. The decision was in the two-year-old case in which the National Association of Performing Artists brought suit against WDAS, Philadelphia, charging that the station broadcast phonograph recordings of music made for home consumption.

In July 1940 however, the U.S. circuit court of appeals upheld the right of radio stations to broadcast phonograph records without paying licence fees to the performers. The supreme court refused to review the appellate court decision, in effect permitting the lower court's ruling to stand.

Property rights of radio dramas were upheld by the circuit court of appeals sitting in Richmond, Va., on Jan. 5, 1942. The Lone Ranger, Inc., owners and originators of *The Lone Ranger* radio program, broadcast on various networks and by transcription throughout the U.S., Canada and Hawaii, had brought suit against Wallace Brothers circus and Lee Powell, an actor, seeking to restrain Powell from representing himself as "The Original Lone Ranger."

Powell had appeared as Allan King, in the motion picture, "The Lone Ranger," produced in 1937. The court decision was hailed as a milestone in legal protection of radio property. The court ruled that the Lone Ranger, Inc., was entitled to protection against unfair competition or "filching" of scripts, personalities or characters.

World Conferences

In the decade 1937-46, one major International Telecommunications conference and several regional meetings by continents and hemispheres were held. They included the following:

The First North American Regional Broadcasting conference in Havana, Cuba, ending Dec. 13, 1937, resulted in a treaty of vital importance to the western hemisphere; the Second North American Regional Broadcasting conference in Washington, D.C., ending Feb. 25, 1946, led to a three-year extension of the North American Regional Broadcasting agreement (N.A.R.B.A.) and adoption of a *modus vivendi*.

The International Telecommunications conference in Cairo, Egypt, Feb. 1 to April 8, 1938, resulted in worldwide radio regulations; it was attended by 285 official delegates from 71 countries and colonies.

The Third Inter-American Radio conference, embracing countries of the western hemisphere, in Rio de Janeiro, Brazil, was held in Sept. 1945.

The United Kingdom-U.S. Telecommunications conference in Bermuda, closing Dec. 4, 1945, resulted in equality of international press communications rates between the British empire and U.S.

The Five-Power Telecommunications Preparatory conference in Moscow, U.S.S.R., Sept. 28-Oct. 21, 1946, made preparations for the World Telecommunications conference, scheduled for July 1, 1947.

The Five-Power High-Frequency (short-wave) conference in Paris, Oct. 28-31, 1946, laid the foundation for a worldwide high-frequency broadcasting organization, the first in history.

The United Nations Telecommunications Advisory committee meeting in Nov. 1946 made recommendations for a world-wide radio network to be operated by the United Nations.

Each regional conference was important to the countries directly affected, but the most important in world-

wide radio broadcasting was the Cairo convention. Here the nations of the world reviewed the entire radio spectrum, made new allocations and drew up new regulations. It was the first international telecommunications conference since the Madrid convention of 1932, and the fifth such assembly in history. Next in world importance was the Moscow Five-Power conference in the fall of 1946.

The various conferences and their relationship to radio broadcasting are discussed in the following chronological order:

North American Radio Conference.—(Havana, March 29, 1937). This was a meeting preliminary to the First North American Regional Broadcasting conference in late 1937. It marked the first time that nations of the North American continent, whose radio problems were mutual, had gathered to discuss ways and means of eliminating intercountry interference and to assure that each nation might use its radio facilities to the fullest degree.

Delegates from Canada, Cuba, the Dominican Republic, Haiti, Mexico and the U.S., after considerable discussion, agreed on the technical principles of broadcast allocations, thereby paving the way for a full treaty conference the subsequent November.

First North American Regional Broadcasting Conference.—(Havana, Nov. 1–Dec. 13, 1937). To the North American continent this was the most important international conference of the decade. Arising from open discussions by delegates of the six countries involved, a note of solidarity was sounded in the redistribution of radio channels. Interference between stations of Mexico and the U.S. and between Cuba, Mexico and the U.S. was abolished as a result of that meeting.

On Dec. 13, 1937, the North American Regional Broadcasting agreement (N.A.R.B.A.) was perfected as the first such arrangement among the North American nations. Under the N.A.R.B.A., high-powered stations on the Mexican border which had been flourishing for some years were eliminated. For a period of years prior to adoption of N.A.R.B.A., so-called "wildcat" broadcasting stations, operating on choice clear channels and with powers of 50,000 watts or more, broadcast from transmitters located just south of the U.S. border in Mexico. In many cases, studios were situated in the U.S.—in southern Texas cities, but the actual transmitters which blasted out powerful signals were in Mexico. Most of those stations were owned by Americans who had been granted concessions by the Mexican government. Some of them had been denied licences by the Federal Radio commission in the U.S. and had established stations just across the border in Mexico.

Under protection of the Mexican government, these "wildcat" stations flourished and set up considerable interference with U.S. stations. In the redistribution of radio channels (frequencies) by N.A.R.B.A., new standards of engineering were adopted, and the signatory nations agreed that no high-powered clear-channel station could operate on the border of any country in which other radio stations were operating on similar frequencies. A total of 106 radio channels were set aside in the spectrum from 550 to 1600 kilocycles. These channels were divided as follows: 59 were designated as clear channels; that is, channels on which high-powered stations could operate with no interference from other stations on the same channel.

Forty-one of the channels were designated as regionals, on which the maximum power was to be 5,000 watts. The remaining 6 became locals, with power not in excess

of 250 watts. The following frequencies, listed in kilocycles, were designated as clear channels: 640, 650, 660, 670, 680, 690, 700, 710, 720, 730, 740, 750, 760, 770, 780, 800, 810, 820, 830, 840, 850, 860, 870, 880, 890, 900, 940, 990, 1000, 1010, 1020, 1030, 1040, 1050, 1060, 1070, 1080, 1090, 1100, 1110, 1120, 1130, 1140, 1160, 1170, 1180, 1190, 1200, 1210, 1220, 1500, 1510, 1520, 1530, 1540, 1550, 1560, 1570 and 1580. Regional frequencies were set aside as follows (listed in kilocycles): 550, 560, 570, 580, 590, 600, 610, 620, 630, 790, 910, 920, 930, 950, 960, 970, 980, 1150, 1250, 1260, 1270, 1280, 1290, 1300, 1310, 1320, 1330, 1350, 1360, 1370, 1380, 1390, 1410, 1420, 1430, 1440, 1460, 1470, 1480, 1590, 1600. The following 6 frequencies, listed in kilocycles, were designated as local channels: 1230, 1240, 1340, 1400, 1450, 1490.

Under the N.A.R.B.A., each signatory nation was permitted to use all of the 106 channels when technical conditions with respect to interference to established stations were such as to render such use practicable. Class I-A clear channels were allocated to the various countries which needed such stations: United States, 25 class I-A channels, (those on which only one station might operate at night); 32 class I-B channels, on which other stations might operate with low power but which had to shield their signals against the dominant stations.

Canada and Mexico were each assigned six class I-A clear channels, while Cuba was allotted one. This resulted in Cuba later filing protest and demanding the use of other clear channels. (This protest and the subsequent outcome is discussed below under the Second North American Regional Broadcasting conference.)

The United States was the first nation to ratify the N.A.R.B.A., the senate approving the treaty on June 15, 1938; on June 30, 1938, it was formally ratified by Pres. Franklin D. Roosevelt. Ratification of the United States was deposited with the government of Cuba on July 21, 1938, and on Jan. 23, 1941, it was proclaimed by the president.

On Oct. 31, 1938, the government of Cuba formally approved the treaty and ordered a reallocation of frequencies in conformity thereto. Canada approved it on Nov. 29, 1938. The Mexican senate on Oct. 26, 1938, declined to ratify the instrument. A year later, however, on Dec. 29, 1939, the Mexican congress formally ratified the treaty, paving the way for placing it in effect. On March 29, 1941, the North American Regional Broadcasting agreement became effective.

International Telecommunications Conference.—(Cairo, Feb. 1–April 8, 1938). Some 400 representatives from 71 countries and colonies attended this, the fifth such international conference on telecommunications in world history. As stated earlier, the nations were represented by 285 official delegates. In addition, 80 representatives attended from 42 operating organizations as well as 27 observers from 14 nonoperating organizations. The United States delegation, headed by Senator Wallace H. White, Jr., Republican of Maine, numbered 60 with staff.

Hassan Sabry Pasha, Egyptian minister of communications, was unanimously elected president of the conference. He immediately named committees to do the preliminary work and make recommendations.

As a result of the Havana meetings in 1937, a group of governments from the Americas proposed that the international short-wave band be expanded to include frequencies from 6000 to 25000 kilocycles. Directive antennas to protect various countries from interference of other nations using the same short-wave channels were discussed in the technical committee, of which White was chairman.

Britain attempted to suppress the commercial broadcasts which literally boomed into the British Isles from stations in France and Luxembourg, by introducing a proposal that no wave band from 160 to 1500 kilocycles could be used by any country in Europe for transmitting "commercial publicity" sent in any other language but the national language or languages of the country originating the broadcasts. The proposal lost by a 17-17 tie vote.

The Cairo conference did extend the broadcast service band, making available several additional international short-wave channels over which various countries could broadcast their own propaganda and beam it to all parts of the world. The following broadcast bands were added to the radio spectrum by the Cairo conference: 25,600-26,600 kc., broadcasting; 26,600-27,500 kc., fixed services on world basis, broadcasting for the U.S.; 27,500, 28,000 kc., radio air soundings; 28,000-30,000 kc., amateurs; above 30,000 kc., regional broadcasting in the Americas and in Europe; 30,000-32,000 kc. low-power stations; 32,000-32,500 kc., maritime beacons; 32,500-50,000 kc., aeronautics; 40,000-40,500 kc., fixed and mobile services; 40,500-58,500 kc., television and low-power stations.

The spectrum from 150-160 kc. was retained for mobile services. The conference allocated to Central American countries for tropical radio use, the band from 4,775-4,895 kc., and assigned to the rest of the tropical regions of the world the band from 4,835-4,965 kc. These short-wave allocations were added to those already in effect since the Madrid conference of 1932: 6,000-6,200 kc.; 9,500-9,700 kc.; 17,750-17,850 kc.; 21,450-21,750 kc.

U.S. newsmen in the White House pressroom on Dec. 7, 1941, as they listened to radio reports of Japan's opening move in World War II

Following the lead of the United States, which earlier had extended the standard broadcast band to 1,600 kc. (the band previously had ended at 1,500 kc.), the Cairo conference agreed to widen the standard band for European use, extending it from 1,500 to 1,600 kc.

Before adjourning, the Cairo conference agreed to hold the next World Telecommunications conference in 1942 in Rome, but of course World War II interfered. The next world conference was scheduled to begin July 1, 1947.

There were regional telecommunications meetings at intervals following the Cairo conference, but nothing on a world-wide or even hemispheric basis until after the fall of Germany in May 1945. On May 7, 1945, the United Nations Conference for International Organization, meeting in San Francisco, pointed to the need for the World Telecommunications conference at an early date and for the free exchange of news and views by all media of mass communication, including short-wave radio, between nations.

Third Inter-American Radio Conference.—(Rio de Janeiro, Sept. 3-24, 1945). This conference was called primarily to discuss rate differentials in various North and South American nations for handling international communications. It developed, however, into an important broadcasting conference, with the Cuban delegation demanding that the Americas draft a new North American Regional Broadcasting agreement.

Canada proposed that the N.A.R.B.A. be extended for two years beyond its expiration date of March 29, 1946. The United States suggested a one-year extension, proposing that in the meantime the Second North American

Regional Broadcasting conference be held. Cuba remained adamant, demanded use of some 20 standard broadcast channels, most of them less than 1000 kc.

As a sidelight to the Rio conference, a group of South American broadcasters laid the foundation for the Inter-American Broadcasting association. They proposed that private industry band together to promote a closer relationship between the nations of North and South America and to resist government encroachment in the field of private broadcasting. The association was proposed by Uruguay and concurred in by Cuba, Mexico, Argentina and several other South American countries. The organization was perfected at a meeting in Mexico City, Sept. 28, 1946.

Bermuda Conference.—(Nov. 21–Dec. 4, 1945). This conference, between the United Kingdom and the United States, had to do exclusively with international communications rates and resulted in the Bermuda agreement, whereby costs of transmitting press messages were equalized by the United Kingdom and the United States. Delegates attended from the United States, the United Kingdom, Canada, Australia, New Zealand, Union of South Africa, India and Southern Rhodesia.

Second North American Regional Broadcasting Conference.—(Washington, D.C., Feb. 4–25, 1946). This conference began as an engineering meeting to discuss minor alterations in engineering standards pending adoption of a new North American Regional Broadcasting agreement. Cuba, however, served notice at the outset that it was prepared to negotiate a new treaty to replace N.A.R.B.A. at its expiration on March 29, 1946.

The United States and Canada opposed a new treaty. Mexico came prepared either to extend the old N.A.R.B.A. or to draft a new one. After two weeks of heated debate, Dr. Luis Machado, vice-chairman of the Cuban delegation, announced that Cuba could not go along with the other nations on extending the N.A.R.B.A. The Cuban delegation was instructed to return home. North American nations, particularly the United States and Mexico, saw untold interference with their own broadcasting stations should Cuba take frequencies at will.

Then followed a series of informal meetings, with T. A. M. Craven, former member of the U.S. Federal Communications commission, who helped draft the original N.A.R.B.A. in Havana, serving as unofficial mediator.

Cuba wanted to use the frequency 640 kc., on which the Bahamas' only station was operating. The Bahamas objected vigorously. A compromise was reached, however, whereby Cuba relinquished its only clear-channel frequency, 1540 kc., to the United States, and in turn received 640 kc. The U.S. then gave the Bahamas clear-channel privileges on the 1540 kc. channel. The switch was completed by Aug. 1, 1946.

Meantime, Cuban stations began intolerable interference on some frequencies in Mexico and the United States. Hardest hit in the U.S. was the channel 630 kc., a regional frequency on which several 5,000 watt stations were operating in the U.S. During the N.A.R.B.A. conference, U.S. station owners protested to the Federal Communications commission; Mexican stations also objected.

On Feb. 25, 1946, Canada, Cuba, the Dominican Republic, the Bahamas, Newfoundland, Mexico and the United States signed an interim agreement, granting concessions to Cuba and extending the N.A.R.B.A. to March 29, 1949. The agreement provided that the various governments make immediate preparations for the Third North

American Regional Broadcasting conference. Canada extended an invitation to meet there on Sept. 15, 1947. But as 1946 closed, the date was moved up to Jan. 2, 1948.

A group of U.S. industry radio engineers met with Federal Communications commission engineers in Washington, D.C., in late Nov., 1946, to prepare U.S. proposals for the forthcoming conference. Engineers in each of the other countries held similar meetings.

Five-Power Telecommunications Conference.—(Moscow, Sept. 28–Oct. 21, 1946). At the Rio conference of 1945 United States delegates proposed informally that the Union of Soviet Socialist Republics might well extend an invitation to the next World Telecommunications conference, to be held some time in 1947. Soviet observers attending the Rio meeting offered the counterproposal, however, that the United States issue the invitation because of disruptions in Europe.

Consequently it was agreed that the U.S.S.R. would invite the United States, the United Kingdom, France and China to a five-power preliminary conference. But months passed and no word came from Moscow. The United States, therefore, notified the Bern bureau of the International Telecommunication union that it would entertain a proposal to hold the next World Telecommunications conference in or near Washington, D.C., beginning about April 1947. Under the Madrid convention it was necessary to have the assent of at least 20 countries to call a conference.

When 20 countries had assented, the U.S.S.R. issued an invitation for the five-power conference in Aug. 1946. Because of the lateness of time the United States and others requested a postponement, which the U.S.S.R. granted. Accordingly on Sept. 28, 1946, delegates of the five sovereign states assembled in Moscow.

That conference was marked by harmony throughout, with the exception that the United Kingdom opposed holding the next world conference in the United States. British delegates insisted it be held in Europe, although Russia, China and France supported the United States. The conference decided that the improvement of the organization of radio communications and the reallocation of radio frequencies to maritime, aeronautical, long-distance land services, broadcasting and other purposes were particularly urgent problems.

A recommendation to convene the next World Radio-communications conference on May 15, 1947, was adopted. The conference also set July 1, 1947, as the date for the next World Telecommunications Plenipotentiary conference and, on motion of the U.S.S.R., agreed to convene a plenipotentiary conference every four years thereafter.

One of the most important recommendations of the Moscow conference was a proposal (submitted by the United States) for the establishment of an international board for the registration of frequencies. Operation of such a board would reduce mutual interference between the radio stations of the world. Another proposal, also submitted by the United States, that the existing International Telecommunications union (I.T.U.) be reorganized and enter into relationship with the United Nations was adopted. An administrative council for the I.T.U. would be formed to include a bureau to control the administrative and technical work of the union. The conference also adopted a recommendation that the seat of the I.T.U. be at the headquarters of the United Nations. Under the recommendations of the five powers, the I.T.U. would be co-ordinated with the U.N. but actually would function as a separate administrative body.

During a meeting of a subcommittee on allocations,

headed by Capt. Paul D. Miles, chief of the frequency service, allocations division, U.S. Federal Communications commission, heated debate arose over extension of the international short-wave band to provide for more radio stations. The U.S.S.R., United Kingdom and France proposed that certain frequencies be taken from the amateurs and allocated to international short-wave broadcasting. With the U.S.S.R., Britain and France all increasing their propaganda broadcasts, beamed to all parts of the world, they insisted that more radio channels were needed. The United States delegates, however, supported by China, opposed additional short-wave channels. Delegates of those two nations expressed the belief that to deprive the amateurs of the frequencies would, in effect, deny the broadcasting industry as a whole valuable propagation information which the amateur operators were able to gather in quantity. Although no formal proposal was made, some members of the United States delegation suggested that all international short-wave stations should be operated in the future by the United Nations, with time allotted to each country for specific broadcasts.

When the United Nations general assembly opened Oct. 23, 1946, at Lake Success, N.Y., the United States made available its international short-wave radio stations for the broadcast in various languages of the important sessions. The U.N. also used the radio to keep the world informed of its progress.

Paris High-Frequency Conference.—(Paris, Oct. 28–31, 1946). This conference followed the five-power assembly in Moscow and was called primarily to discuss the international short-wave situation, which had become acute following World War II. During the war, as the axis countries and satellites fell, the Allied nations expropriated various frequencies used by the axis nations. As a result, the end of 1946 saw considerable interference in some quarters of the world. The United States was using some 50 or more frequencies, although under the Madrid convention half that number was officially assigned. Great Britain and the U.S.S.R. likewise were using more than their share as assigned by the Madrid convention.

It was generally agreed at the Paris conference that the solution rested in a world-wide high-frequency conference—the first of its kind ever held. The delegates (U.S.S.R., United Kingdom, France, U.S. and China) adopted a recommendation to call a world-wide short-wave broadcasting conference in 1947, to follow the Radiocommunications conference, scheduled to open on May 15.

Meanwhile, the short-wave stations of the world were being operated by the various governments at the close of World War II. Prior to the war, the stations of the United States were operated by private industry. After the U.S. entered the war, however, the Office of War Information (OWI) was established and by agreement took over the programming of the various stations (18 at the outbreak of war). When World War II ended, the United States was operating 36 short-wave stations on 56 frequencies. When OWI was dissolved by President Truman in late 1945, its informational functions were transferred to the state department, which continued to operate the short-wave stations, although the latter were licensed by the Federal Communications commission to private industry.

For many months the U.S.S.R. had objected to the broadcast of Russian-language programs by either Great Britain or the United States, unofficially, on the grounds that the soviet people were told what the soviet government deemed best for them, and that presenting a variety of facts might confuse their minds. Nevertheless, Great Britain began the broadcast of Russian-language programs

in the summer of 1946. France announced similar intentions, but at the close of 1946 had not begun the programs. The United States got Russian-language broadcasts under way shortly after the end of the decade—on Feb. 17, 1947. William Benton, assistant secretary of state in charge of cultural affairs, conferred in Moscow with soviet officials regarding an interchange of students between the U.S.S.R. and U.S.A. Meanwhile the soviet union was broadcasting several hours daily in the English language and beaming the programs to English-speaking nations, including the United States.

(J. N. B.; R. W. CR.; S. T. F.)

Scientific Developments

Considerable technical progress was made in radio during 1937–46. The principal progress in the fields of propagation, navigation, tubes, frequency modulation and facsimile is summarized in the following sections.

Radio Wave Propagation.—Major progress in this field was in research and correlation of results of ionosphere studies and the application of this knowledge to commercial operation of radio transmitting and receiving equipment. Prior to 1937 the engineering design of radiating systems (antennae), particularly for generating and collecting medium and high-frequency radio waves, had been hindered by lack of such knowledge and information. It was now possible to design radiating systems in accordance with the principles derived by research to utilize the propagation phenomena for most efficient radio use.

There are three general forms of wave propagation—surface or ground wave propagation, skywave propagation by reflections from the ionospheres, and optical or quasi-optical propagation.

Ground waves are utilized for the lowest radio frequencies, from 10 to approximately 3000 kc. For a given radiated power over typical land surfaces, the rate of decay of signal strength *v.* distance, increases with frequency and with the average resistivity of the soil or earth. Over sea water, the rate of decay is much lower than that of the best earth because of the relatively low resistivity of salt water, so that much greater distances can be covered with given power over sea than over land. Ground waves are so called because their utilization depends upon the nature of the electromagnetic fields at the boundary between the wave in the atmosphere and the accompanying ground currents propagated in the earth below it. For most effective utilization the wave must be vertically polarized; *i.e.*, the electric vectors lie in vertical planes extending in the direction of propagation.

Skywaves are so called because they are propagated in space above the earth and reflected earthward from regions of high free-electron density in the upper atmosphere called ionospheres. The ionospheres thus act as imperfect mirrors for radio waves roughly between 500 and 30,000 kc. Typical propagation over great distances may involve several reflections between earth and ionosphere before arriving at a distant receiving point. The waves travelling in the atmosphere between these boundaries decay at a rate which is inversely proportional to distance. The reflection coefficient of the ionosphere depends upon the particular layer used, the frequency, the angle of incidence and the immediate state of ionization in the ionosphere layer, this latter being dependent upon solar ultraviolet radiation, sunspot activity and the consequent state of the earth's magnetic field. The layers are seriously disturbed by sunspots, magnetic storms and aurora borealis.

The ionosphere layers were studied very extensively by adaptation of radar principles, two principal layers were found, these were designated as the E and F regions, the latter was divided into two normal layers during local daylight hours called F_1 and F_2 . Other layers often exist transiently. The E layer exists during daylight only, and has a stable height of approximately 170 km. At night there is one stable F layer with a nominal height of the order of 300 km. After local sunrise, sunlight ionization of the upper atmosphere causes the formation of the E layer, and the break-up of the nighttime F layer into the F_1 at roughly 230 km. average height and the F_2 at heights from 325 to 450 km. After local sunset, deionization commences with the disappearance of the E layer, and the convergence of F_1 and F_2 layers into the F which alone remains throughout the hours of darkness. Just before local sunrise, the electron density in the ionosphere is at its lowest and transmission during this period requires much lower frequencies and much higher power than at other times of the day.

There are critical frequency waves which penetrate these layers and are not reflected. The optimum working frequency for radio transmission is usually 15% below the critical frequency for normal incidence at the point of reflection. This optimum frequency varies throughout the day and night, necessitating changes in operating frequencies over fixed radio circuits for best transmission efficiency. The Central Radio Propagation laboratory of the national bureau of standards, co-operating with agencies throughout the world operating continuous ionosphere sounding stations, continued to compile and publish complete ionosphere data monthly during the decade.

Medium-frequency broadcasting (550-1600 kc.) provides primary service with ground waves and sometimes an intermittent skywave service at night. Usually skywaves and ground-waves overlap at distances from 35 to 100 mi. from a broadcast station where severe rapid fading results at night. Skywaves between stations are also a serious source of interference. The years 1937-46 saw great strides in the development, design and installation of special directive antennae to permit several broadcasting stations to operate on the same frequency satisfactorily.

At frequencies above those which are reflected by the ionosphere (roughly above 30,000 kc.) radio propagation becomes optical or quasi-optical in character. Within radio-optical line of sight, signals are propagated in the space immediately above the surface of the earth, by direct optical transmission. Because of the very narrow angles subtended by practical heights of transmitting and receiving antennae at distances of several miles, the received wave is the composite of the ray transmitted directly in free space, and one or several rays which have been reflected from the ground, the latter of opposite phase and very nearly the same amplitude. High resultant field strengths at distant points are obtained only by providing circuit geometry which will avoid this normal tendency to complete cancellation near the ground so that the distance travelled by the reflected ray is at least one-sixth wave length greater than the direct ray. The lower the frequency, the higher must be the transmitting and receiving antennae above the ground level to achieve this.

Beyond the radio-optical horizon, the field present is due to diffraction. At frequencies below about 150,000 kc., useful service can exist in the diffraction region, thus extending the distance which can be covered from a given antenna height. Above this frequency the diffraction zone

virtually vanishes, and transmission distance approaches that of the optical horizon. It was found that frequencies above about 5,000 mc. are affected by meteorological conditions and the state of the atmosphere which produce transient mirage effects, absorption and dispersion.

Radio Navigation for Sea and Air.—During the decade vast numbers of radio navigational systems, primarily for use as aids to aviation, were proposed. Both war and peace made demands upon engineers for methods of removing the fundamental obstacles to all-weather flying and instrument landing and for safety of life and property. Of the many systems proposed, only a few could find wide application because of the need for broad standardization within a country and preferably throughout the world. After 1944 most of the nations united in the Provisional International Civil Aviation organization (P.I.C.A.O.) for the purpose of standardizing equipment and procedures for international aviation, including radio navigational and instrument landing aids. In 1946 extensive demonstrations were made in England, the United States and Canada of many systems prior to the P.I.C.A.O. deliberations leading to adoption of preferred systems.

Radio navigational systems were broadly classified as radial(R-O), hyperbolic and pictorial. The radial systems provide linear course guidance, and position by triangulation with two or more separate radial courses. The hyperbolic systems provide courses or line of position which are generally curved in the form of hyperbolas, and position is determined by the intersections of two or more hyperbolic lines of position. The pictorial systems are those which present to the navigator a map or "picture" of the surroundings and his position on that map. The latter was the latest type of system.

Under the radial system were included the following systems actually placed in use:

Radio direction finding by means of manual and automatic radio compasses, used by ships and aircraft for many years.

The CAA four-course low-frequency radio range system, used throughout the United States and Canada, and during World War II extended throughout the world. (Short and medium distances depending upon natural noise levels.)

The CAA two-course very high-frequency aural-visual radio range, used on portions of the United States airways. (Short distances.)

The CAA very high-frequency omni-directional radio range (originally developed and proposed by the Radio Corporation of America), providing an unlimited number of radial courses. (Short distances.)

The U.S. army SCS-51 and the CAA Instrument Landing system runway localizer and glide path systems, providing lateral and vertical linear guidance for landing aircraft. (Very short distances.)

The Sonne system of angularly moving radial equisignal linear courses developed in Germany and using the low frequencies. It is a long-range navigational system, using the triangulation between two stations to give a fix.

Under the pictorial system were the following systems, one of which was in use and the other in development at the end of 1946:

The plan-position-indicator form of microwave radar system for use on ships, whereby reflections from objects on or above the water reflect radar echoes which are luminously displayed in the form of a map on a cathode-ray indicator tube, with the ship as the centre of the map. It was put in use on ships, for navigation in coastal areas and for collision prevention.

The Teleran system, proposed by Radio Corporation of America, used an integrated system of ground-search radar, altimeters in the aircraft and television to display, on the ground and in each aircraft, a selected map of any of a number of vertical strata showing navigational, meteorological, traffic, ground-controlled traffic instructions and geographical information on a cathode ray tube; and in the aircraft to identify one's own aircraft with respect to all others. This system was being developed for the U.S. army at the end of the decade.

Other special aids were required, such as position marker beacons, radiophares, radio altimeters and distance-measuring equipment. The latter, utilizing the principle of transponders, or pulse repeaters, made use of the echo-time for radar pulses transmitted from the aircraft to a ground point and return, and displayed as a direct reading of distance. When used with a radial navigational system the navigator was provided with both azimuth and distance from a station on the ground. Such a system combination gave the polar co-ordinates of the aircraft's position with respect to the ground station and was therefore classified as a radial system.

Under the hyperbolic system were the following systems actually in use (omitting reference to a large number of proposed systems not in use at the end of the decade):

The loran system (long range navigation), using the principle of measuring the time-difference of arrival of synchronized pulses from two or more geographically separated transmitters, using medium frequency.

The Gee system (British) of time-difference measurement of synchronized pulses from three transmitters spatially separated, for short-range navigation, using very high frequencies.

The low-frequency loran system, (U.S.) similar to the preceding but using much lower frequencies.

The Decca system of navigation (British) using low frequencies and operating on a phase-comparison method of indication.

Tubes.—During the decade, tubes were improved materially, both in terms of power output and operating frequency. The ability to generate more power at higher and higher frequencies was due to improvements in triodes and tetrodes and the introduction of tubes operating on new principles.

Triodes and Tetrodes.—In the generation of power at high frequencies with conventional triodes and tetrodes, the dimensions of the electrodes must always be a fraction of a wave length. Thus, as the frequency increases (or the wave length decreases), the physical dimensions of the tubes become smaller and consequently the ability of the tubes to handle power decreases. For any given method of cooling, the power output should vary with the inverse square of the dimensions of the electrodes. On this basis the power-handling ability of tubes can only be increased if the method of cooling the electrodes can be improved or if electrode materials can be found which will stand a higher thermal loading. During the years 1937–46, tube power ratings at any given frequency increased because of improvements in electrode cooling. In 1937 for example, it was possible to generate only about 100 watts at 300 mc., whereas in 1946, 5,000 watts could be obtained. Again, at 100 mc. only 500 watts could be generated with one tube in 1937, but in 1946 over 25,000 watts could be obtained.

There were similar advances in the circuit applications of triodes and tetrodes at high frequencies. In 1937 it was difficult to construct amplifiers above 50 mc. as triodes alone were available, and it was often impossible to neutralize them so that the amplifier would not oscillate.

In 1946 tetrodes were available for use up to 300 mc., and triodes had been designed for use in the so-called grounded grid circuit which permitted stable amplification at high power and high frequencies. Triodes were used as amplifiers in the grounded grid circuit at frequencies as high as 3,000 mc.

Transit-Time Tubes.—The greatest advances of the decade in extending the useful frequency spectrum were made by the development of electron tubes in which the time of electron transit was of the order of the radio frequency period. The numerous military radar equipments used during World War II were responsible for greatly accelerating the development of transit-time tubes. Tubes of this general type could be employed as amplifiers and efficient oscillators at frequencies as high as 40,000 mc. (0.75 cm. wave length). Here again physical limitations were encountered since the small size of resonant systems make it impractical to dissipate heat, although no purely electronic limit existed.

Transit-time tubes could be divided into the following four specific types on the basis of their principle of operation.

1. Electron-beam deflection-modulation tubes.
2. Electron-beam velocity-modulation tubes.
3. Multi-resonator magnetrons.
4. Travelling-wave tubes.

The first two types operate on the principle of transferring energy between electrons and radio-frequency fields in a time small compared with one period, and long transit time in regions free of radio-frequency fields is utilized to accomplish the desired results. The operation of the last two types is dependent upon the more or less continuous transfer of energy between electrons and radio-frequency fields travelling at almost equal rates. The energy transfer may occur during a period amounting to several radio-frequency cycles. The following paragraphs describe the basic method of operation of each of the four types.

Beam-Deflection Tubes.—In this type of tube a beam of electrons passes between deflecting plates connected to the radio-frequency circuits. The beam is therefore laterally deflected by the varying radio-frequency potential, and the deflected beam is caused to impinge on separate collector plates during opposite half cycles. By suitable design of the collector structure, the tube may be used as an ultra high-frequency detector, mixer, frequency multiplier and, with proper feed-back connection, as an oscillator.

Velocity-Modulation Tubes (Klystrons).—Velocity-modulation tubes operate by using the radio-frequency field between two grids to vary the velocity of electrons passing through these grids. The electrons are then allowed to drift in a region free of radio-frequency (r.f.) fields until they are "bunched." This bunching occurs because electrons passing through the grids early in the radio-frequency cycle are retarded, those passing when the r.f. field is small are unaffected and those passing later are speeded up. The length of drift space is such that at the time of maximum bunching the bunch passes through grids connected to a second radio-frequency circuit. Such a tube acts as an amplifier.

A tube of this type was developed as a "reflex" oscillator in which the field-free drift space was replaced by a retarding direct current field set up between the second grid and a "reflector" electrode. The reflector potential and distance from the grids could be adjusted to bunch the electrons and return them through the grids in proper phase to produce oscillations.

Multi-Resonator Magnetrons.—In a magnetron, electrons emitted from an axial cathode under the influence of a radial D.C. electric field and an axial magnetic field execute spiral cycloidal-like orbits around the cathode. In the multi-resonator magnetron, the anode is formed of many metallic segments connected to suitable radio-frequency resonant circuits. The fringe radio-frequency fields between these segments interact with the rotating electron cloud in such a fashion that there is a net transfer of energy from D.C. electric field to radio-frequency field. The radio-frequency fields between the anode segments may be considered as made up of travelling waves around the electron interaction region, in which the rotating electron cloud moves in synchronism with the radio-frequency wave.

Magnetron oscillators were used as both pulsed and C-W generators at wave lengths from 0.5 cm. to 50 cm. For pulsed tubes the upper limit to peak power at the end of the decade was about 100 kw. at 1 cm., 3 megawatts at 10 cm. For C-W tubes power ratings ranged from 10 kw. at 50 cm. to almost 1 kw. at 3 cm.

Travelling-Wave Tubes.—An experimental travelling-wave tube was announced by the Bell Telephone laboratories. This type of tube obtained its transfer of energy from a moving electron stream to a travelling radio-frequency wave by applying the wave to a helix of iron wire surrounding the electron stream. Because of the reduction in wave-velocity caused by the radio-frequency fields proceeding along the turns of the helix, the electron velocity could be adjusted to exceed slightly the effective wave-propagation velocity down the helix and thereby transfer electron energy to the wave. Useful amplification of 100 to 200 with a band width of approximately 800 mc. was claimed for tubes of this type.

Receiving Tubes.—New tubes were developed which made it possible to produce radio receivers giving satisfactory performance in the microwave region. Improvements in the performance of tubes suitable for the lower frequencies were realized. Some of the more important developments in the receiving-tube field are discussed in the following paragraphs.

The Lighthouse tube, developed primarily for military applications, was useful up to about 4,000 mc. Its name was derived from its general appearance. In this tube a flat disk-shaped grid of wire mesh was interposed between the ends of two cylindrical members forming the cathode and plate electrodes. This construction minimized lead inductance since the cathode and plate connections were simply extensions of these electrodes, and connection to the control grid was made around the circumference of the grid disk just outside the glass to the metal seal. The rigid disk seal construction made possible the close electrode spacing required in order to obtain high mutual conductance. It also provided low plate-to-cathode capacitance required for grounded grid applications.

Beam-deflection tubes were developed for frequency-converter applications (for principle of operation, see above). In such tubes the electron beam was deflected simultaneously by the received signal and local oscillator voltages applied to separate deflection plates. This type of tube made it possible to minimize input electrode conductance.

The Reflex Klystron (see above) was used as the local oscillator in superheterodyne receivers in that portion of the frequency spectrum where conventional types of tubes no longer gave satisfactory performance. This type of tube

operated at frequencies up to approximately 20,000 mc.

The Orbital-Beam tube employed secondary emission principles to obtain improved performance. The input section of the tube consisted of a tetrode having a mutual conductance in the region of 3,000 micromhos. The plate of the tetrode, however, acted as a secondary emitter, having a secondary emission ratio of about 5 to 1 which increased the over-all mutual conductance to 15,000.

During the decade there was a general trend toward reducing the size of many receiving-type tubes. This trend was accelerated by World War II, and large quantities of subminiature tubes were manufactured for the proximity fuse. In many instances the use of miniature tubes made possible a considerable reduction in the over-all size of the equipment.

Special Purpose Tubes.—The Cyclophon, an electronic beam switching tube, was developed by the Federal Telecommunications laboratories. An electron gun, similar to that employed in conventional cathode-ray tubes, produced a narrow electron beam. Electrostatic or electromagnetic deflecting means caused the beam to rotate at constant velocity and to trace a circular pattern on an aperture plate in which were cut a number of uniformly spaced slots or apertures. The number of apertures corresponded to the number of circuits to be switched. Tubes using 8 and 24 apertures were designed. Behind each aperture was a secondary emission dynode. Electrons produced by secondary emission, when the electron beam traverses these dynodes, were collected by the aperture plate. If a series resistance was connected in each dynode circuit a voltage drop would exist across the resistor while the electron beam was traversing the dynode. Cyclophon tubes were employed as pulse generators in time-division multiplexing systems and in switching or commutating circuits.

The Phasitron was a special electronic tube for producing a frequency-modulated signal. The tube required for its operation a crystal-controlled source of three-phase energy at a submultiple of the desired carrier frequency and also a source of modulating energy. It was constructed with focusing electrodes to produce a disk of electrons at right angles to the axis of the tube. Another set of electrodes, energized by the three-phase source, deflected the electrons radiating from the centre of the disk so as to produce rotating radial undulations in the surface of the disk. The intercept of the disk on an imaginary cylinder whose axis was common to the axis of the disk would be a sine wave of a frequency equal to that of the three-phase deflecting source.

The disk of electrons terminated on two concentric cylinders, the innermost of which had a series of rectangular holes so arranged that if the rotation of the disk were arrested at the correct position, nearly all the electrons would pass through the holes to the second cylinder. A half wave displacement of the disk would result in all the electrons being caught by the first cylinder. It was thus obvious that there would be an alternate collection of electrons by the two cylinders which could be used to excite a tuned circuit connected between the two cylinders. Phase modulation of the energy in the tuned circuit connected between the collector plates was accomplished by means of a coil external to the tube with its axis coincident with that of the tube. When this coil was energized from a modulating source, its magnetic flux caused electrons starting at the centre of the disk to be deflected from their normal radial path and produced the effect of momentarily speeding up or slowing down the sine-wave pattern on the collecting cylinders, depending on the polarity of the flux.

Frequency Modulation.—Frequency modulation (FM)

was introduced during the decade as a new sound broadcasting service. In FM the intelligence is transmitted by variation of the frequency of the radiated wave instead of its amplitude as with amplitude modulation. Prior to World War II, the frequency band from 42 to 50 mc. was assigned to FM broadcasting. With the objective of minimizing the effects of propagation vagaries, the Federal Communications commission in 1945 shifted the frequencies allocated for FM broadcasting to the band from 88 to 108 mc. The channel width employed for FM broadcasting was 200 kc. and the maximum deviation was 75 kc.

Two general types of transmitters were employed for FM broadcasting. In the first type the phase of the carrier frequency wave, derived from a crystal-controlled oscillator was varied directly in proportion to the strength of the modulating signal. In order to obtain frequency modulation with this system, the modulating signal was first passed through an attenuating network which caused the output voltage to vary in amplitude inversely proportional to the modulating frequency. A special tube called the Phasitron was developed for use in transmitters of this type (see under *Tubes*, above). In the second type of transmitter the frequency of a self-excited oscillator was varied in accordance with the modulating signal. The variation in frequency was accomplished by means of reactance tubes connected in shunt with the oscillator tank circuit. In order to obtain the desired mean frequency stability in transmitters of this type, the frequency of the self-excited oscillator was compared with the frequency of a crystal-controlled oscillator and some automatic means was employed to correct for the frequency drift which might otherwise occur in the self-excited oscillator.

The receivers developed for the reception of FM signals could be classified into three general types. The first type employed a limiter stage in combination with a balanced discriminator. The limiting action was usually obtained in the intermediate frequency-amplifier stage which preceded the discriminator. The balanced discriminator operated to balance out the effect of amplitude modulation on the received wave. The second type employed a continuously operating oscillator the frequency of which was controlled by the frequency variations of the received signal. The oscillator was responsive to frequency variation only and was not affected by amplitude modulation of the received signal. The output voltage from the oscillator was applied to a discriminator-detector combination. A special discriminator-detector combination known as a Ratio-Detector was employed in the third type of receiver. In this arrangement the output currents from two diodes were caused to flow through a common-load resistor. The sum of the voltages across the resistor was automatically held constant. The potential derived from one diode therefore could not increase without a corresponding decrease in the potential from the other. The audio output voltage was derived from the variation in the voltage across either one of the diodes. Amplitude variations in the received signal caused the rectified current through the common load resistor to change but did not affect the audio output voltage.

Facsimile Equipment.—During the decade 1937-46, the field of facsimile advanced in strides comparable to those of other branches of electronics. During 1937-40, the Radio Corporation of America manufactured home facsimile equipment which brought the morning news to families in several cities of the United States. Wire photo service progressed throughout the world, especially in the United States, where circuits were established by the major news services, whose pictures were received from every major city of the United States and distributed daily to

the U.S. press. Radio facsimile transmissions on a world-wide basis were used commercially during 1936-41. After the United States entered World War II, the army, navy and the Office of War Information (OWI) developed radio-photo networks which encompassed the entire allied world. These world-wide circuits were made technically possible by the development of frequency modulation for the audio spectrum. By using this type of modulation, the carrier of the transmitter was kept 100% modulated at all times, thus decreasing the signal-to-noise ratio which in turn gave pictures with fewer interference lines.

Tape facsimile for wire and radio circuits also saw considerable advancement during World War II and was widely used by both the U.S. army and navy.

After World War II ended, interest was revived in facsimile, and many of the former OWI world-wide circuits were taken over by U.S. communications companies. Broadcasting stations showed considerable enthusiasm in the commercial possibilities of home facsimile, as did many foreign newspapers and governments.

Cultural Aspects

The ten-year record of radio broadcasting, in terms of its cultural aspects, was a record as full of as many positive and negative factors as are the electrical particles themselves that make up the broadcasting waves.

For over this decade the world-wide use of radio broadcasting ranged from the extolling of the dubious virtues of dubious medicines, to the furthering of the even more dubious qualities of political tyrannies, to the great symphonies, the great plays and the great ideas of all time brought into the homes of everyone.

The impactful quality of radio—the fact that in an instant great masses of people could be reached in the privacy of their own homes—made radio, in this turbulent decade, the propaganda tool for those who had something to sell to the mass of people, from the sale of carloads of soap flakes to the acceptance of the idea of world domination.

The result was that as an educative force, radio fulfilled its promise largely in those nations wherein the radio structure was not dominated either by state or profit-minded agencies. But in spite of this emphasis upon commercialism in some sectors and propaganda in others, great masses of people were able to hear for the first time, and at practically no cost, the truly great music of all time.

In spite of the infantile dramas of the "villain-still-pursued-her" category, the good of the theatre and the best of thoughtful original radio drama reached the ears of millions. The egomanias of self-styled nation saviours might have misused the microphones—yet simultaneously countless others were reached in their homes by words of statesmanship.

At the close of the decade, technological advances forecast the opening of thousands of interference-free channels, available at low cost to cultural groups, reaching the remotest corners with the good of radio broadcasting.

The succeeding decade, then, could anticipate a greater, more forceful and more mature use of radio broadcasting as a means not only for amusement but also, and most importantly, for the mental growth of the world of peoples anxiously sitting on an atomic time bomb. (A. Or.)

Radio in Other Countries

The beginning of 1937 was noteworthy for several events in the history of the development and application

of radio waves for a variety of purposes. The broadcasting of entertainment and news items had become a necessary adjunct of everyday life in most of the civilized countries of the world; and it was on Jan. 1, 1937, that the British Broadcasting corporation received a new charter whereby it could continue to maintain a service, controlled by government administration but unhampered thereby and free to develop and exploit to the full the technique of broadcasting not only by sound, but also by television. The use of short radio waves from 15 to 100 m. in length for broadcasting on a world-wide basis was firmly established, and the first public television service in the world had just been inaugurated from London. Still shorter radio waves, a few metres in length, had already been applied with considerable success to short-distance radio links forming an integral part or extension of the normal land-line telegraph and telephone system. Progress in the application of radio to communication with ships at sea was exemplified by the equipment fitted in the "Queen Mary," then the latest representative of the class of express passenger liners. The installations on this vessel provided for high-speed transmission and reception, and telegraphic or telephonic communication with both sides of the Atlantic during her normal routine voyages between Europe and the U.S. Amid this wealth of application of known principles, there were being conducted in England, Germany and Italy, the first serious experiments in the technique of radiolocation or radar (*q.v.*)

Broadcasting.—During 1937–46 radio broadcasting progressed in two phases; the first during the period 1937–39, when broadcasting stations in Europe were being developed, installed and arranged according to the international Lucerne plan of 1934; and later when broadcasting became an effective weapon of war for the distribution of news and propaganda as well as entertainment. At the end of 1937 it was estimated that there were nearly 32,000,000 holders of receiving licences in Europe, of whom some 8,000,000 were in Great Britain and Northern Ireland, the latter rising to about 10,000,000 in 1946. To provide for the vast listening population associated with these licences, there was a steady development and improvement in the whole technique of transmitting a broadcasting program, from the design of studios with good acoustic properties to the increase in efficiency and stability of the sending stations themselves.

In order to accommodate as many broadcast sending stations as possible within a given frequency or wave-length band without mutual interference, the carrier frequency of each station must be kept as constant as possible. This technique advanced so much in this period that the frequencies of many of the best broadcasting stations were ultimately maintained constant to better than 1 part in 1,000,000; and as an incidental advantage the waves from such stations could be used as a standard of reference for frequency-measuring purposes. As a result of this technical achievement it became possible to operate two or more stations in different areas of the same country on the same frequency and broadcasting the same program. The high standard attained in this technique in Great Britain by 1939 was put to immediate strategic use on the outbreak of World War II, by grouping all the stations in the country on two wave lengths only, and emitting what became known as the home service.

In this way, axis aircraft were prevented from using the

British broadcasting stations as radio beacons for navigational purposes.

The early period of the war demonstrated the importance of broadcasting for propaganda purposes and for the dissemination of news to axis-occupied countries, as well as for the entertainment of military forces at home and abroad. In view of these facts, jamming systems were developed to prevent listeners from hearing axis transmissions. This naturally gave rise to the development and installation of higher power and more effective transmitters. In Great Britain these developments culminated in the completion of the world's most powerful broadcasting station, capable of delivering 800 kw. to the aerial on either long or medium waves.

Similar developments took place in the use of short-wave broadcasting to considerable distances, such as from England to places outside Europe. While Great Britain was a pioneer in the development of short-wave broadcasting above all in the provision of an empire service, other countries, particularly Germany, Italy and the United States, were active in this field before 1939. During the first year of World War II it became clear that a considerable expansion of the dozen or so short-wave transmitters in Great Britain with output powers of 50 kw., was necessary in order to carry the many and varied programs required as part of the war policy. As a result, the world's largest short-wave broadcasting station was built in 1943 in the north of England: it had 2 separate installations comprising 12 100-kw. transmitters and a system of 51 aerials. With the aid of this station and its previously existing short-wave installations, the BBC could, during the latter years of the war, broadcast simultaneously on 43 separate short wave-lengths and its transmitters were used to radiate not only the "Voice of Britain" to the world, but also the "America Calling Europe" programs, which were relayed by short wave radio beams from U.S. to England.

Associated with this great development of transmitting stations was that of sound broadcasting technique, since it is of great advantage, particularly in short-wave broadcasting, to be able to repeat programs several times within a 24-hour period, in order to suit the convenient listening times in the countries receiving them. Improvements were made in Great Britain in the technique of recording on steel tape and on metal disks coated with cellulose acetate; while considerable advance was made in Germany with a technique of recording on a plastic tape coated with an iron powder film, which offered certain advantages over the steel tape.

(R. L. S-R.)

British and European Programs.—The chief categories of radio programs were all well established, in Great Britain and western Europe at least, when 1937 began. What happened to them during the next ten years? And why? The answers to these two questions were bound up with the whole history of Europe during those appalling and eventful years.

The biggest single influence on the radio program during the greater part of this period came from Germany: it could be summed up in the one word—propaganda. "Without loud-speakers," said Adolf Hitler, "we could not have conquered Germany."

With the help of loud-speakers Hitler hoped to conquer Europe and the world.

The nazis were anticipated by the soviet government in the conscious use of radio as a medium of propaganda to their own and foreign peoples. By 1937 they were far ahead in the vigour and persistence with which they used

On-the-spot broadcast by a U.S. soldier, near St. Paul's cathedral, relating his impressions of the bombed city of London over the British Broadcasting company network in 1942

what seemed to them the medium's most effective possibilities; 1937-41 were the years of their sensational success. Outside broadcasts from mass meetings, marching songs and "front reports" from the advancing German armies, commentaries which purported to come from the air raiders over Britain all helped to build up the picture of overwhelming, ruthless, irresistible German might.

That the German radio lied without scruple or system did not matter to Dr. Josef Goebbels. He was out for quick returns. He exploited to the full the mass emotions of the German people. He exploited to the full the fears and grievances and internecine hatreds of the peoples who were threatened by the Nazi boot. Above all, he exploited the universal passion for quick and precise "news." These were the peak years of Nazi radio programs—the years when false news won enormous audiences because it was first in the field, when glib traitors like Paul Ferdonnet of Stuttgart and William Joyce of Bremen ("Lord Haw Haw") won enormous audiences by their skill in twisting unspoken prejudices and dumb grudges to suit their ends, when the rhythmical tramp and rhythmical songs of the armies of Germany seemed to fill the ether and hypnotize the peoples of Europe into acquiescence or collapse. Goebbels' radio programs may have been crude and repetitive. Their brutal falsity excluded them from any hope of success in the documentary or historical or radio drama fields. The quick returns at which they were aiming were obtained in the fields of outside broadcasting and "news" and propaganda talks, cunningly baited with much first-rate music and many catchy tunes.

These methods assumed quick victory and lived by it alone; from the end of 1941 onward they began to defeat themselves as final victory slipped farther and farther out of the Nazis' grasp. The audience was satiated with propaganda; it was also beginning to doubt. The propaganda programs began to lose their audiences abroad as well as at home. Radio subscriptions began steadily to fall off in the western occupied countries, except in France where more and more people were acquiring sets on which to listen to the voice of London. "Lord Haw Haw's" audiences in Great Britain had thrived on curiosity for some months; they were falling steadily before the year 1941 began. In response to the demands of soldiers and workers more and more space had to be left for jazz and other forms of banned entertainment in the German home programs.

Most significant of all, a mass of evidence showed "black listening" was on the increase among the people of Germany and the occupied countries. The broadcast programs of the British Broadcasting Corporation (BBC) were beginning to make their influence felt on a considerable scale. These programs represented the first authentic answer of free Europe to Dr. Goebbels. They had begun with a tentative whisper in three languages on Sept. 27, 1938. They had been gaining in scope and stature ever since. In 1943 the peak was reached when the BBC disseminated its news in 48 languages and dialects.

It is difficult to estimate the true importance of this influence in Europe. It is impossible to contest its growth from long before the end of 1941, perhaps from the critical days of 1940 when Europe's exiled leaders and rulers such as General Charles de Gaulle, Queen Wilhelmina of the Netherlands, King Haakon VII of Norway and General Wladislaw Sikorski of Poland spoke to their countrymen. Many tributes were paid to these foreign-language services by men and women to whom they brought encouragement and hope in the blackest days. One name may be

cited to symbolize their most outstanding triumph. The brilliant political dialogues and satires of the Free French team of broadcasters headed by Jacques Duchesne had probably never been excelled in their own most difficult and subtle field.

In a different style, "Colonel Britton's" talks, which introduced the famous V-sign, were addressed to the underground movements of Europe.

The English-language programs of the BBC reacted to the stimulus of Dr. Goebbels in even more effective and independent terms. Here was no attempt at direct competition, no effort to out-lie or to out-boast or to out-prophecy. Objective news was the slow but effective answer to "hot" lies. Straight talks, expository or descriptive, critical or hortatory, were the answer to appeals to prejudice and hate. Up-to-date listener research maintained a constant check on what the home listening audience wanted in many fields of culture and information and entertainment.

Thus the BBC's programs met the three great appetites which World War II had immensely sharpened among listeners, without sacrificing its standards of integrity and without ignoring the wishes of audiences in the supposed higher interest of some political scheme. BBC met the hunger for news by a greatly increased stream of factual news bulletins, coupled with large numbers of topical and explanatory news talks, and from 1942 an ever-increasing volume of direct war reporting, culminating in the remarkable series of war reports which were broadcast from D-day to May 1945.

The 6:00 P.M. and 9:00 P.M. British news bulletins of the home service constituted recognized listening "peaks" which could be said with certainty to attract from 10,000,000 to 15,000,000 of the potential radio audience in Great Britain. A news postscript like that of Quentin Reynolds in Aug. 1940 attracted 17,000,000 listeners. A commentary on an air battle off Dover by Charles Gardner in July 1940, attracted 21,000,000. This news service was both vivid and up-to-date; so the announcements of the fall of Keren in Abyssinia (March 27, 1941), of the overthrow of Mussolini (July 25, 1943), of the Paris rising (Aug. 22, 1944), and of the Rumanian capitulation (Aug. 23, 1944), followed almost immediately upon the events and broke the news to the English-speaking peoples. Secondly, they met the need for stimulating and informing the home public by a varied selection of feature programs and talks of all kinds. The "service talks" of John Hilton and many others explained the intricacies of wartime regulations with remarkable success. Feature programs like "The Harbour called Mulberry" (March 1945) attracted an audience of 9,000,000. Any broadcast by Winston Churchill was listened to by 25,000,000 in Great Britain alone.

The success of the "Brain Trust" over several years showed how widespread was the popular desire for general knowledge. Finally the BBC met the human needs of its uprooted audiences in the armed forces with its specialized forces programs, while "Itma" with its seven years of performance was probably the most striking of the BBC's many wartime successes in the light entertainment field.

The end of World War II brought with it a reaction against wartime stresses, and the BBC responded in many various ways. Not that it dropped its objective information service to listeners at home and in Europe. But with the inauguration of the third program on Sept. 29, 1946, it launched a remarkable cultural experiment, which made possible the performance of many full-scale musical and dramatic works running for two hours or more. It returned with added vigour to the development of regional broad-

casts which war needs had reduced to a small scale.

With the lessons of the war and the warning of the Goebbels experiment behind it, its radio programs were setting an example which the free broadcasting organizations of western Europe seemed more and more disposed to imitate in many fields. Radiology

Radiology made significant progress in its own realm during the decade 1937-46 and contributed not a little to developments in other branches of science. Activities in radiology may be divided into several categories. Originally appearing with Wilhelm Roentgen's discovery of X-rays as a branch of physics, it continued as an important subdivision of the physical group of sciences through development in the many phases of radioactivity. It also became instrumental in adding knowledge to certain phases of chemistry because of the ability of short wave radiations to indicate the ultimate structure of matter; to biology in shedding light upon cell structure, mechanics and genetics; to the basic medical sciences by revelations in anatomy, physiology and pathology and in industry and engineering with numerous applications to their problems. (See X-RAY.)

Though the auxiliary applications of radiology to the various sciences grew in importance, the greatest field of application during the decade was still to medicine in the diagnosis and treatment of disease. In these fields, many advances were made in improvements of techniques, refinements in diagnostic methods, development of greater accuracy in diagnosis and extension of the field of usefulness. While many of these advances were not sufficiently new to justify reporting here, the total represented a significant increase in the utility of radiology to the practice of medicine. The diversion of energy into channels required by World War II reduced the amount of original research in the last half of the decade except in those portions related to atomic fission. Early in the postwar period, evidence of renewed activity in fundamental new research appeared from many quarters.

Radioactive Isotopes.—Probably the most important developments were in connection with the use of radioactive isotopes. These modified elements, having the same chemical properties as the normal elements, may be injected in small quantities for tracer studies or in larger amounts for their therapeutic effect. The absorption, distribution and excretion of the isotopes may be studied by observing the radiations which they give off as they disintegrate. Featuring prominently in this type of research during the decade were phosphorus, iron, iodine, strontium and sodium.

Radioactive phosphorus was shown to localize in the bones, liver and spleen of normal people and in the white blood cells and bone marrow of leukaemic patients and in the characteristic cells of those with lymphosarcoma. In addition to knowledge of the pathological physiology of these diseases, larger doses of radiophosphorus, injected intravenously, were used successfully in their treatment. Radioactive iron was used in studies of the blood in normal individuals and in anaemia and with radiosodium in studies of the mechanism of shock and on the fate of cells after transfusion. Radioactive iodine contributed considerable knowledge to the physiology of the thyroid gland and goitre and showed some possibilities of use in the treatment of diseases of this gland. Radioactive strontium was found to localize in the growing portions of bones, suggesting that this substance might eventually prove useful in the treatment of bone tumours. Much of this work was interrupted by World War II, as materials and the energies of atomic physicists were devoted to military objectives. Numerous additional isotopes were made available, though in limited quantities, by the process of atomic fission, and would be available for future research.

Basic Science.—Of fundamental importance to radiology was the invention of the betatron. Though not yet applied to medicine in 1946, the very high voltages possible indicated that future therapeutic methods would be strongly influenced by this instrument. Measurements on phantoms indicated that the depth dose could be controlled in a more effective manner because the dose is a function of the voltage. As the voltage was increased the plane of maximum dosage became deeper. At 20,000,000 volts the maximum effect was about ten centimetres below the surface.

Considerable interest attached to studies in the field of biological chemistry and the structure of proteins by Roentgen-ray diffraction. Investigations were made in egg albumen, haemoglobin, nerve tissue, on the function of enzymes and the effect of formaldehyde on proteins.

Studies by means of the Roentgen-rays contributed materially to certain phases of anatomy and physiology, giv-

ing information obtainable in no other way. Previously, many anatomical studies had to be made only on the cadaver and physiological studies on animals or isolated tissues. By means of Roentgen-ray methods large numbers of living, healthy subjects of different ages could be studied. This type of observation was particularly fruitful in surveying the time of appearance and rate of development of ossification centres and in studies in the gross anatomy and physiology of the gastrointestinal tracts of infants.

Contributions were made to both anatomical and physiological fields with the development of angiography—study and description of the blood vessels. Successful angiography was dependent upon two new developments—the discovery of nontoxic opaque substances which are miscible with the blood stream, and the development of cine-fluorography. Two classes of opaque materials may be used: thorium dioxide sols or organic iodine bearing compounds such as are used in intravenous pyelography. Cine-fluorography made rapid strides with the advent of brighter fluorescent screens, better lenses and faster photographic emulsions, so that excellent moving pictures of the fluorescent image may be made. The opaque material is injected into the appropriate artery or vein and rapid serial exposures made immediately thereafter. With these improvements it became possible to demonstrate the circulation in the heart and the great vessels in both human and animal subjects. Especially interesting studies appeared on the foetal circulation in sheep and the changes occurring at birth.

Medical Diagnosis.—Angiography was successfully used also in the diagnosis of certain types of congenital heart disease. Injection of opaque material into the carotid arteries enabled excellent visualization of the intracranial circulation, assisting in the diagnosis of aneurysms and anomalies and in the localization of tumours as well as the detection of other diseases. In a similar manner the abdominal vessels were visualized, revealing various types of arterial disease not previously demonstrable.

Considerable improvement and extension of utility of venography by opaque media were made. This proved particularly useful in determining the condition of the venous circulation in varicose veins and thrombophlebitis.

The investigation of diseases of the small intestines attracted considerable attention. In certain states of vitamin deficiency, degenerative changes occur in the nerve plexuses resulting in dysfunction of the musculature giving a characteristic appearance in the roentgenograms.

The field of usefulness of radiology in obstetrics was extended, and the utilization of studies by X-ray became more generally accepted. Most of the techniques of pelvimetry had long been known, but there were many improvements in these techniques. Better methods for the localization of the placenta were developed. The Roentgen rays became generally useful in the diagnosis of renal complications of pregnancy by the extended use of intravenous pyelography.

Body section roentgenography introduced about the beginning of the decade underwent a great deal of development and became generally adopted. This technique of examination appeared under many synonyms: laminography, planigraphy, stratigraphy and tomography. The method consists in moving an X-ray tube in one direction while the film is moved in the opposite, about a fixed axis. The level of the axis may be placed at any plane in the body. The shadows of all objects in the plane of the axis

will be sharp while those above and below will be blurred. This type of examination proved of great value in many fields, particularly in the radiography of the temporomandibular joint, the nasal accessory sinuses, the larynx, the sternum and in many diseases of the lungs.

Photofluorography, the indirect Roentgen examination by photographing the image on a fluorescent screen, was developed and brought to a high state of refinement. This type of apparatus became particularly useful in examining large numbers of patients in a short time, such as surveys for tuberculosis and the examination of recruits for the armed forces. The principle of all was essentially the same; the image on a bright fluorescent screen is photographed with fast lens on a fast photographic emulsion. Film sizes from 35 mm. up to 4 x 5 in. are used. The resulting film is read by projection or magnification. By this method it is possible to examine as many as three patients a minute. It was felt at the end of the decade that this type of examination was not yet suitable for accurate diagnosis, but was adequate and efficient for screening the normal from the diseased individuals.

Radiation Therapy.—In the realm of X-ray and radium therapy, significant advances were made in many directions during the decade 1937–46. Of basic importance in the treatment of cancer were numerous studies upon the effects of various types of radiation on cells as well as the effects of intensity, dosage and fractionation. While all these results had not yet been applied to practical irradiation by the end of the decade, certain fundamental facts were emerging: that cells are most sensitive in the premitotic phase, that there is a critical range of intensity below and above which radiation becomes less effective, and that most effective fractionation probably can be accomplished by co-ordinating it with the cell types of the tumour, possibly with change in the rate of fractionation as treatment progresses and the characteristics of the cells become altered as a result of the irradiation.

One characteristic of development in radiation therapy of the period was that of supervoltage machines, up to about 1,000,000 volts. Supervoltages gave promise of better results because of the better depth dose and reduced superficial reactions. Many reports from various sources appeared on results of treatment showing improvement in the percentages of five-year cures and decreased undesirable reactions. While the results were encouraging, they did not equal the hopes aroused by the first enthusiasm for supervoltage treatment.

Irradiation had been known for many years to be of benefit in certain acute infections. During the decade this aspect of therapy spread in scope and became more generally accepted. Although the use of radiation in these conditions was purely empirical, it was shown to be useful in pneumonia, sinusitis, postoperative parotitis, acute peritonitis, gas gangrene and numerous localized infections.

Interesting reports appeared of changes in bone following deep X-ray treatment. Fractures of the femur following treatment to lesions within the pelvis, fractures of the ribs after irradiation of lesions of the breast and aseptic necrosis of the skull after treatment of intracranial lesions were reported, some appearing as long as 15 years after the original treatment. Successful treatment of radiation dermatitis with alpha ray ointment was developed.

Apparatus.—A very useful piece of new apparatus for roentgenology was invented—the Morgan exposure meter. This is a device using two photoelectric tubes which automatically time the exposure. Accurate duplication of exposure is possible regardless of voltage within reasonable limits. The meter may be adjusted to give any de-

sired quality of film. This device proved of inestimable value in mass surveys. (See also CANCER.)

Radium

While small amounts of radium are associated with the vanadium and uranium ores of the western U.S., recovery of the radium received little attention during the years of World War II. The last output officially reported during the decade 1937-46 was 2.6 grams in 1942. Imports of radium salts into the U.S. were as follows:

	Grams	Value		Grams	Value
1937	15.29	\$ 377,659	1942	23,043	\$ 377,326
1938	38.75	787,025	1943	90,755	1,366,538
1939	78.631	1,953,820	1944	101,290	1,374,933
1940	30.311	748,097	1945	67,342	991,979
1941	4.412	110,202			

Demands for war uses, especially for industrial radiography and in luminous paints, overshadowed the normal medical uses during the decade. (G. A. Ro.)

Raeder, Erich

Raeder (1876?-), German naval officer, was born in Wandsbek, Germany. He entered the German navy in 1894, rising to the rank of commander in 1911 and was made chief of staff to Adm. Franz Ritter von Hipper in 1912. Raeder participated in several naval engagements in World War I, escaping from the German flagship "Lutzow" before it was sunk in the battle of Jutland in 1916.

After the war, Raeder headed the central department of the reich naval office. In 1922, he was promoted to rear admiral and inspector of naval education; six years later he was promoted to admiral at the head of the naval command. Raeder supported the nazis, and in 1935 was rewarded by Adolf Hitler with the post of commander in

chief of the German navy. In 1939, he was promoted to the rank of grand admiral.

Chief architect of the Germany navy during the peace years, he ordered construction of new vessels in secret violation of the Versailles treaty. He originated the plan for the invasion of Norway in 1940, and directed the navy's plan of unrestricted submarine warfare.

Raeder retired from the navy at his own request, Jan. 30, 1943, and was succeeded by Admiral Karl Doenitz. He was taken prisoner by the Allies after the collapse of Germany in May 1945 and was indicted Aug. 29, 1945, on charges of war crimes. Convicted on Oct. 1, 1946, by the International Military tribunal sitting at Nuernberg, he was sentenced to life imprisonment for having committed crimes against the peace and war crimes.

Railroad Retirement Act

See SOCIAL SECURITY.

Railroads

Throughout the ten eventful years ending in 1946 there were wide variations in the yearly railroad transportation product in ton-miles and passenger-miles, railroad gross revenues and net income, number of employees and their compensation and the statistical units which reflect the degree of operating efficiency. During 1937, the first year of the decade, there were indications that the adverse forces of the depression which began late in 1929 had been spent, and that the United States was on the road toward an early recovery from the worst economic setback in its history. The partial recovery, however, was retarded by the "recession" of 1938. Conditions became better in 1939, but uncertainty and confusion followed the beginning of World War II when Germany overran Poland and the armed conflict began among Germany and the allied forces of England and France. Throughout 1940 the national economy of the United States was disturbed by the war in Europe. In 1941 the program of national defense and the inauguration of material assistance in lend-lease to the nations aligned against Germany virtually brought the United States into the war. The Selective Service act had been passed, the United States began to build up an army of defense, and the transportation activities were on a large scale. Then came the Japanese attack on Pearl Harbor and the declaration of war in Dec. 1941. From then until V-J day in Aug. 1945, the U.S. railroads, dedicated primarily during the war years to military ends, met the unprecedented transportation demands with adequate service.

Following the capitulation of Germany in May 1945, the transportation pattern changed materially. In the expectation that the war with Japan would continue many months, plans were made to deploy the armed forces from Germany to the Pacific theatre, and movement of troops, equipment and supplies back to the United States and then to the Pacific was under way when Japan surrendered in August. Then came the reverse movement from the Pacific ports to the separation centres throughout the country for demobilization. The overload on the railroads continued well into 1946.

Changes in U.S. Track Mileage.—During the decade 1937-46, the mileage of railroads in the United States had a steady but slight downward trend. The miles of newly constructed lines were less than the miles abandoned because of unprofitable operations. The process of abandonment was stimulated by the urgent need of scrap steel, and

Armoured tanks rolling out of the Proviso, Ill., yards of the Chicago and North Western railroad for shipment overseas during World War II

that need had influence upon the Interstate Commerce commission, without whose permission the unprofitable segments in a railroad system could not be abandoned. The line mileage of Class I railroads (those having annual operating revenues of \$1,000,000 or more—constituting about 95% of total mileage and earning about 97% of total operating revenues) dropped from 223,962 in 1937 to 215,403 on Jan. 1, 1945.

These data are for miles of line and do not reflect the miles of track on the average mile of line. On Jan. 1, 1937, there were 370,992 mi. of Class I tracks, including the first running track, multiple running tracks and sidings and yards. This track mileage had been reduced to 355,880 by Jan. 1, 1945.

The inauguration of lightweight streamlined passenger trains in the early '30s, and the rapid increase in the number of such trains run at relatively high speed, were accompanied by programs of line straightening, curve reduction, improvements and extensions in signalling, deeper ballast under the track and higher standards of maintenance of track, roadway and structures. In some cases the physical betterments included reductions in the rates of the grades and relocation of the line. While these improvements were stimulated mainly by the need of ways over which the high-speed passenger trains could be operated safely, they were of benefit also to freight service, in which the average speed of trains was materially increased. Coincident with the betterments on the line, corresponding improvements were made in terminals, notably in freight classification yards. Programs for such work, well under way in 1930, were suspended or curtailed during the depression but were resumed in part during the late '30s and pushed forward vigorously when World War II began in Europe.

Investment of these large additional capital outlays at a time when railroad net earnings were low, and the potential competitive effect of newer forms of transportation was uncertain, called for courage on the part of railroad managers. Their faith in the railroad as the prime mover among the transportation agencies was justified by the commendable performance of railroads during World War II. If the improvements which brought increases in capacity to handle traffic had not been made before the United States entered the war, the unprecedented transportation demands might not have been adequately met.

Locomotives and Cars.—In U.S. locomotives and cars, there were moderate reductions in numbers. The new units added, however, were of greater power and capacity than the old units retired, and the proportion of the total in unserviceable condition was less. There was, therefore, little change in the aggregate power and capacity available for service. The number of locomotives on Class I railroads on Jan. 1, 1937, was 44,347. The comparable number on July 31, 1946, was 42,520. The loss of 4% in number was offset by a gain of 10% in average tractive capacity per unit and a reduction in the per cent unserviceable from 22 to 15.

An important development during the decade was the large increase in the number of diesel-electric locomotives. First employed in the '20s for switching service, the diesel was next used generally on streamlined passenger trains. Its efficiency and suitability for heavy passenger trains was demonstrated, and it was rapidly displacing the steam locomotive on lines with heavy traffic. Its use in freight

service was also becoming general. During the decade, the number of diesels ordered by railroads of the United States was nearly three times as great as the number of steam locomotives ordered. In 1945, for example, the total orders for 856 locomotives comprised 702 diesels, 148 steam and 6 all-electric.

Experiments were made in other types of locomotive and in new types of fuel. The steam turbine locomotive showed promise, and the use of powdered coal as fuel gave good results.

There was a striking development in lightweight streamlined passenger cars for name trains operated at high speed. The serious decline in U.S. rail passenger traffic in the '20s and early '30s had held back orders for new cars. As the old were retired they were not replaced. The number of passenger train cars on railroads of all classes in 1921 was 56,950. As of Jan. 1, 1937, it was 40,949. On Jan. 1, 1945, it was 38,217. The railroads, in the late '30s, undertook extensive measures to regain some of the passenger traffic lost to the automobile and the bus and to meet the new challenge of the aeroplane by modernizing their passenger train equipment, increasing train speed and adding to the comfort of passengers.

The number of freight cars owned by U.S. railroads of all classes showed little change between 1937 and 1946. At the beginning of the decade it was 1,766,428, and on Jan. 1, 1945, it was 1,797,012. These figures do not include the privately owned freight cars of the packers, fruit growers associations, oil companies and others which numbered 290,668 in 1937 and 270,936 on Jan. 1, 1945. The principal development in freight cars was an increase in the average tonnage capacity, a decrease in its tare weight by the use of metal alloys and plywood in construction, improved air brakes and high-speed trucks. The average weight capacity in 1937 was 49.2 tons. In 1946 it was about 51 tons.

Financial Organization.—The findings of the Interstate Commerce commission in its reports on physical valuation of railroads (under the Valuation act of 1913) indicated clearly that the cost of reproducing the properties, minus an allowance for physical depreciation, was greater than the capitalization. From the viewpoint of actual cash investment in roadway, structures, real estate and equipment, U.S. railroads collectively were not overcapitalized, but in many cases the capitalization was greater than justified by net earnings.

One weakness in the typical railroad financial structure was that the amount of borrowed money was substantially in excess of the amount of money risked by the owners. Borrowed money, in large part, was secured by bonds which were a mortgage on the property and a first lien on net earnings. If the interest was not paid currently, or if the principal was not paid when the bonds matured, the railroad was likely to go into receivership or trusteeship, and the control of the property would pass from the owners (the stockholders) to the courts which acted for the protection of the bondholders and other creditors. This weakness in the capital structure led to serious trouble in the early years of the depression, when net earnings were insufficient to service the debt. In 1934 there were 80 railroads in the hands of receivers or trustees. Their mileage was 42,168, or 17% of the total. On Dec. 31, 1939, the number of bankrupt roads rose to 108, with a mileage of 77,013, almost one-third of the total mileage. After 1939 the reorganization of several railroads was completed, and the properties emerged with a much sounder capital structure.

On Dec. 31, 1945, the number of railroads still in process

of reorganization and in the hands of the courts was 75, with 41,154 mi. of line.

As a result of reorganization, under court proceedings, of 33 railroads after 1939, and the successful efforts of other railroads to revamp their capital structure without court proceedings, the balance sheet of the railroads as a whole in 1946 showed a material improvement over that of 1937. Total capitalization had been reduced, notwithstanding substantial additional investments in betterments, and, even more important, the ratio of fixed interest-bearing debt to total securities was cut down. A substantial part of the fixed interest bonds was converted into income bonds or debentures on which the interest charges did not have to be paid currently if they were not earned. These interest charges, therefore, were contingent on earnings, and failure to pay did not necessarily lead to bankruptcy. Table I shows the nature and extent of the changes between Dec. 31, 1937, and 1944 of railroads as a whole (excluding switching and terminal companies).

Table I.—U.S. Railroad Capitalization
(in millions)

Item	1937	Per cent of total	1944	Per cent of total
Common stock	\$7,790	35.9	7,464	38.5
Preferred stock	2,023	9.3	1,984	10.2
Total capital stock	9,813	45.2	9,448	48.7
Mortgage bonds	9,331	43.0	8,393	43.3
Collateral trust bonds	812	3.7	394	2.0
Income bonds and debentures	313	1.4	528	2.7
Miscellaneous obligations	871	4.0	39	0.2
Equipment trust notes	555	2.6	600	3.1
Total funded debt	11,882	54.8	9,954	51.3
Total capitalization	21,695	100.0	19,403	100.0

The figures in Table I require qualification. They represent the total amount of securities issued and outstanding. Inasmuch, however, as about one-fifth of the securities were held by the issuing railroads or by other railroads which had used them in part as the underlying security for collateral trust bonds, the net capitalization in the hands of the public was considerably smaller. The net capitalization is shown in Table II.

Table II.—U.S. Railroad Securities in the Hands of Nonrailroad Holders
(in millions)

Item	1937	Per cent of total	1944	Per cent of total
Capital stock	\$7,069	39	6,964	43
Funded debt	11,250	61	9,312	57
Total net capitalization	18,319	100	16,276	100

Several railroads used a substantial part of their war years net earnings to purchase their own securities. Others were successful during 1943-45 in refunding maturing issues of bonds in smaller amounts and at lower interest rates. As a consequence of that process, and of the reorganizations in bankruptcy proceedings, the fixed interest charges on funded debt of Class I railroads were reduced from \$441,000,000 in 1937 to \$382,000,000 in 1945. These reductions in capitalization and interest charges were more noteworthy when consideration was given to the fact that the net additions and betterments to the properties during those eight years added more than a \$1,033,333,333 to the railroad investment account of Class I railroads.

Volume of U.S. Railroad Traffic.—In 1937 the volume of rail traffic was markedly subnormal as a result of the depression. The volume in 1938 was even lower. An improvement was apparent in 1939. Then came the beginning of World War II with its stimulating effect on industrial output and transportation demands. Each year from 1940 to 1945 there were continued increases in the numbers of tons and passengers moved by U.S. railroads. Further

increases were arrested by the surrender of Germany in May 1945, and the capitulation of Japan three months later. The traffic volume of 1945 was somewhat less than in 1944. In 1946 the ton-miles were about 15% less and the passenger-miles about 29% less than in 1945.

Table III shows the traffic volume and the length of the haul in selected years of the decade under review.

Item	1937	1940	1942	1943	1944	1945
Revenue tons originated (millions) . . .	1,016	1,009	1,421	1,481	1,491	1,425
Revenue ton miles (billions)	361	373	638	727	737	681
Revenue passengers (millions)	497	453	667	882	910	894
Revenue passenger miles (billions) . . .	25	24	54	88	96	92
Miles per originated ton	337	351	428	469	473	477
Miles per passenger per R.R.						
Suburban	17	17	18	17	17	17
Others	82	88	123	144	152	151
All passengers	50	52	80	100	105	103

The movement of military personnel and freight during World War II had a marked effect on the average distance per passenger (per railroad) and the average miles per originated ton (all railroads considered as one system). The average miles per passenger, exclusive of commutation (suburban) service jumped from 82 in 1937 to 152 in 1944. The average haul per originated ton rose from 337 in 1937 to 477 in 1945. In terms of volume, the ton-miles increased more than two-fold and the passenger-miles in 1944 were nearly four times the volume of 1937.

By far the greater part of the gain in railroad traffic in 1942-45 was in military supplies and equipment and in movement of military personnel, both under orders and while on furlough. Coupled with these movements on passenger trains was a large volume of civilian travel to and from the training camps and other military establishments. During the years of World War II, about 90% of the military freight and about 98% of organized groups of military personnel moved by rail. The remainder was moved by highway, inland waterway and air.

U.S. Railroad Record in World War II.—In contrast to U.S. railroad performance during the first ten months of World War I, when serious congestion and inadequate service led President Wilson to take over the railroads for governmental operation, the railroads throughout all of the four years of World War II, under private ownership, satisfactorily met all of the heavy military transportation demands without congestion, car shortage or unreasonable delay. And this was done with the minimum of sacrifice on the part of the civilian population. Railroad performance brought high praise from the military heads and other governmental officials.

In tons hauled 1 mile, the best quantitative measure of freight service, the production in 1944 was more than twice that of 1937. In passengers carried 1 mile, the 1944 production was nearly 4 times that of 1937. Or if the records of World War II be compared with those of World War I, the figures would show that in 1944 the ton-miles were 124% more than in 1918 and the passenger-miles 82% more. Furthermore, the larger volume in 1944 was handled with 32% less locomotives, 24% fewer freight cars, 30% less passenger train cars and 23% fewer employees than in 1918.

This achievement was the result of intelligent and forward-looking planning in prewar days and distinct progress in managerial technique. The achievement, however, would not have

been possible without the large measure of co-operation from shippers, government agencies and the travelling public. From shippers the co-operation took the form of minimizing freight car needs by reducing the time taken by loading and unloading and by loading more tons into each car. Through the Regional Shippers Advisory boards there was free and helpful interchange of suggestions and advance notice of car requirements. Complete and cordial liaison with the quartermaster general's organization and the bureau of supplies and accounts of the navy brought about an effective and continuous understanding of military transportation needs. Continuing contacts with the Office of Defense Transportation and the Interstate Commerce commission brought help from those bodies when help was needed, and on the part of the public there was ready acceptance of curtailment in service and little complaint about crowded and late trains.

From the experience in World War I, the railroads learned to do better and avoided their earlier mistakes. Through an organization created in the early '20s, in which the army and the navy were represented, plans were made and periodically reviewed so that in the event of another war the military needs would be known and the railroads would be prepared to meet them. The smoothness with which the early transportation demands were met in the hectic days following the attack on Pearl Harbor was proof of the thoroughness and efficacy of earlier planning.

Revenues, Expenses and Net Earnings.—Contrary to a widely held opinion among the general public, the U.S. railroads as a whole did not make large net profits during World War II. It is true that gross earnings were higher than ever before, but the large increases in revenues were accompanied by corresponding inflation in the cost of wages and materials, and taxes were nearly six times as great in 1944 as in 1937. During the four years (1942-45) when the United States was at war with Germany and Japan, the gross operating revenues of Class I railroads were \$8,715,000,000 per year. The corresponding figure for the four predepression years (1926-29) was \$6,228,000,000. Yet after the payment of the higher operating expenses and taxes and the somewhat lower fixed charges, the yearly net income was \$722,000,000. The corresponding figure for 1926-29 was \$791,000,000. The net income during World War II, therefore, was 9% less than in the predepression years.

Table IV contains a condensed income account of Class I railroads in 1929, a prosperous predepression year; 1937, in which there was an upturn in business after six years of depression; 1940, a prewar year in which business conditions were fairly normal; and the four war years, 1942-45.

It will be noted that the stockholders did not earn as much in net income in the war years as they did in 1929. The dividends declared in 1926-29 averaged \$433,000,000 per year on an investment of about \$24,000,000,000. During the 9 years of depression they were \$185,000,000 per year (declared largely from surplus) on an investment of about \$26,000,000,000. The dividends in the war period were about \$220 annually. A substantial part of the net income of the war years was used by management for capital additions and betterments to property and to pur-

chase their own securities in the open market.

Quality of Service.—Throughout the depression, when railroad traffic, especially in the passenger department, was critically low and a large part of capacity was not utilized, the railroads did well in maintaining the quality and adequacy of service. Some regular trains were withdrawn, and the abandonment of unprofitable branch lines, which were sapping the strength of the main lines, was stimulated. As a whole, however, an earnest effort was made to improve rail service and meet the intensified competition of carriers by highway, water and air. Freight service was speeded up, and additions were made to the fleet of scheduled fast freight trains.

The most notable development was the inauguration of lightweight streamlined trains operated at high speed. In 1935, there were 14 of these trains in operation. To these, 22 were added in 1936, and there were 46 by the close of 1939.

In 1946, the number was about 70, with others under construction.

In addition to the name trains, with lightweight equipment hauled by diesel locomotives, there were notable improvements in the design of the cars used in conventional trains with steam locomotives, and the speed of those trains was stepped up. During World War II, the railroads were unable to obtain priorities for the construction of urgently needed additional equipment. When the ban was lifted a few months after V-J day, orders for large numbers of cars of modern design were placed and some of them were delivered in 1946. Air conditioning became standard on all new cars for through trains; toilet, dressing and lounge facilities were made more ample; more attention was given to design, colours and decorations; and the lighting arrangements were materially improved. In sleeping cars the

provision of separate rooms, displacing the conventional berths, met with definite public approval.

An interesting innovation on one road was a de luxe passenger car with a second story covered by a dome-shaped roof made of glass.

Freight and Passenger Rates.—The critical financial condition of the U.S. railroads in 1937 led them to ask the Interstate Commerce commission for permission to increase freight rates. The request was granted in small part. It was equivalent to an advance of 2%. Considering the increase as inadequate, the railroads petitioned the commission to reopen the case, and after further hearings an additional advance of about 5% was approved.

The railroads in eastern territory, late in 1937, sought the commission's approval of an increase in the coach passenger fare from 2 cents to 2.5 cents per mile. This the commission denied in April 1938, but on rehearing and further consideration the commission reversed itself and permitted the 2.5 cent rate to go into effect for 18 months. About the same time the commission permitted an increase of 5% in charges for space in sleeping and parlour cars. The Pullman company had asked for 10%. In another case, decided in Feb. 1939, the commission authorized a small increase in the rates charged by the Railway Express agency.

When the 18 months time limit on the increase in coach fares expired in Jan. 1940, the commission extended the period 3 months, but after further hearings ordered that the 2-cent rate be restored from March 25, 1940. In Feb. 1942 the railroads were permitted to increase the rate 10% to 2.2 cents. That rate was still in effect at the end of 1946.

The first of the commission's decisions in the Southern Governors' Rate Case became effective on March 1, 1940. The south had contended that it had been retarded economically by freight rate barriers. The decision required adjustments in rates on a limited number of manufactured and processed articles moving between the north and south. The majority of the commission (it was a 5 to 4 decision—2 members not participating) found that higher rates from south to north placed southern producers at an undue disadvantage.

The decision, however, did not end the case. The commission later began a comprehensive investigation of the entire class rate scales of north, south and west and, as a so-called "interim measure," ordered the railroads, effective Nov. 30, 1945, to increase the class rates in the north 10% and to reduce class rates in other territories (except west of the Rockies) by the same percentage. The commission further required the railroads, as soon as practicable, to bring about uniformity in the classification which designated the classes into which each commodity fell. The development of the classifications in the several rate-making regions had gone on independently in each region, and there was conspicuous lack of uniformity.

Acting on the petition of the governors of nine north-eastern states, the federal district court in northern New York granted an interlocutory injunction in Dec. 1945, enjoining the enforcement of the commission's order requiring a 10% increase in class rates in the north and a 10% decrease in the south and parts of the west. Thereupon the commission ordered an indefinite postponement of the rate changes until the legal questions were cleared.

In April 1943 the commission, because of the improvement in rail earnings, ordered the railroads to suspend certain of the freight rate increases which had been approved

Electric locomotive of the GG-1 type for the "Broadway Limited," running between New York city and Chicago

in March 1942. The suspension was to continue until June 30, 1944. Later the suspension was further extended, and the case was merged with the broader issue when the railroads, in May 1946, asked for a general increase of 25% in freight rates. The substantial increases in labour and material costs had had a serious effect on net income beginning in the second half of 1945. The hearings began on May 6, 1946, and on June 29, as an emergency measure to afford partial and temporary relief while further consideration to the subject would be given, the commission authorized rate advances of approximately 6.5%. The extent of the increases varied between regions according to the commission's views concerning relative needs. While the temporary and inadequate relief was welcomed by the railroads, they pressed for prompt action on their plea for the full 25% increase. (During the first half of 1946 the net railway operating income was insufficient to cover all fixed charges.) The commission promised to expedite the proceedings; further hearings were held, but at the end of 1946 the matter was still under consideration.

The average revenue per ton-mile and per passenger-mile are measures of the unit prices paid by the public for transportation service. These units were affected directly by the general scale of rates but they were influenced also by changes in the proportions which the various commodities and types of passengers bore to the totals and by the length of the haul.

One significant change in the policy of the Interstate Commerce commission may be mentioned. At many times during its 60 years of service, the commission had considered requests to approve rates which for commodities in trainload lots would be lower than the rate for a single carload. All such proposals had been disapproved, principally because the lower trainload rate might give big business an undue advantage and might work to the detriment of the small shipper. This policy was reversed in Dec. 1939, when the commission approved a proposal of southern railroads to grant preferential rates on trainload lots of blackstrap molasses from New Orleans to points in Illinois.

Operating Efficiency of Class I Railroads.—During the decade, U.S. railroads made notable gains in the efficiency of operation, especially during World War II. Of special interest was the higher utilization of the potential capacity of freight locomotives and freight cars at a time when there was ever-present danger that a freight car shortage might develop. An increase of 1 mile in the average daily miles-per-freight-car was equivalent to adding approximately 100,000 cars to the available supply. A part of the gain in efficiency was due to the increased volume of traffic which permitted more complete utilization of capacity. Part was attributable to additional capital outlays for

improvements in plant and equipment. Still another part was due to advances in the technique of management. And finally a substantial part was due to assistance from outside—co-operation from the Office of Defense Transportation, the Shippers Advisory boards and the individual shippers.

Approximately three-quarters of U.S. railroad gross revenues came from the movement of freight. The efficiency of freight train and freight car performance, therefore, was highly important. The economic objective was to get the maximum number of ton-miles (producing revenues) with the minimum number of train-miles (representing costs). In the case of freight cars the objective was to produce the maximum in ton-miles with the minimum in car-days.

In the predepression year 1929 with the heaviest volume of traffic up to that time, the average freight train had an average net load of 804 tons. During the depression years, with subnormal traffic, the net trainload dropped as low as 663. In 1937 it was 796. In 1941 it was increased to 915 and during the years of World War II it increased steadily, reaching an all-time high of 1,139 tons in 1944. Because of a slight decline in traffic, it dropped to 1,129 in 1945 and in the first 7 months of 1946 it was 1,055.

While the trainload was of high importance from the viewpoint of operating efficiency, the average speed of the train between terminals was also important. Some costs were proportional with train-miles but the greater part ran with train-hours. In 1929 the average speed of freight trains, terminal-to-terminal including road delays, was 13.2 m.p.h. In 1937 it was 16.1 m.p.h. The very heavy volume of traffic during World War II caused more road delays in meeting and passing other trains, and the average speed dropped to 15.7 m.p.h. in 1944 and 1945. During the first 7 months of 1946, with slightly less traffic, it rose to 16.1 m.p.h.

The resultant of these two factors—the trainload and the train-speed—is net ton-miles per train-hour, the tons moved hourly one mile by the average freight train. In 1929 the figure was 10,580. In 1937 it was 12,695. The comparable figure in 1944 was 17,621 and in the first 7 months of 1946 it was 16,806. These figures indicate that the hourly production of the average freight train in 1944 was 66% better than in 1929 and 39% better than in 1937.

There is nothing romantic about a freight car, but it is the moneymaker for the railroads. Much depends upon its daily productivity in ton-miles. It was the most vulnerable spot in railroad armour in the successful struggle to meet the intensive freight transportation demands while World War II was in progress.

The freight car is in motion in trains an astonishingly small part of its time. By far the greater part of its drab life is spent in movements to and from outlying yards and freight station or on loading and unloading tracks, in classification yards, at junction points between railroads, in

shops for repairs, and at freight stations or on industrial sidings. During World War I, the average freight car moved about 24 mi. per day.

From lessons learned in the war experience in 1917-18, railroad managers were made conscious of some of the weak spots, and in planning for World War II they set about to reduce delays for which

Table VI.—Freight Car Performance, Class I U.S. Railroads

Item	1929	1937	1940	1942	1943	1944	1945	First 7 mos. of 1946
Car-miles per serviceable freight car-day	34.4	36.6	38.9	48.8	51.0	51.9	48.1	42.8
Tons per loaded car-mile	26.9	27.1	27.6	31.8	33.3	32.7	32.2	30.9
Per cent loaded of total car-miles	62.8	63.0	61.8	62.8	64.2	65.8	67.0	66.4
Ton-miles per serviceable freight car day	582	625	664	975	1,092	1,114	1,005	841

railroads were responsible and to enlist the co-operation of shippers and receivers of freight to cut down the detention for which they were responsible. The objectives were to cut down the idle hours in yards, terminals, freight houses and shops, to get a heavier carload, and to increase the per cent loaded of total car-miles. The results for 1929 and in selected years of the decade under review are shown in Table VI.

The most striking fact in the foregoing statistics is that ton-mile productivity of the average freight car in 1944, when freight car utilization was vital, was nearly double that of 1937.

Labour Relations.—The relations between management and the railroad labour unions during the decade 1937-46 were strained on several occasions when disputes grew out of demands for wage increases and changes in working rules. Two of these disputes led to temporary seizure of the railroads for government operation, and in one of them there was a nationwide strike which paralyzed railroad service for two days.

In the wage controversies, management usually dealt collectively with two groups of unions. The first, known as the operating group, was made up of the train service brotherhoods and yard switchmen, five unions in all. They numbered about 250,000 men. The second, known as the nonoperating group, numbering about 800,000 employees, was comprised mainly of the shop crafts, maintenance-of-way employees, stationmen, clerks and others affiliated with 15 separate unions. Management thus had to deal with 20 unions in 2 loosely-knit groups.

Early in 1937 the operating group demanded a wage increase of 20%. Simultaneously the nonoperating group asked for a pay boost of 20 cents per hour. After long drawn out direct negotiations and intervention by the National Mediation board, the differences were settled by mutual agreement, effective Aug. 1, 1937. The operating group received an increase of 5.5 cents per hour and the nonoperating group received 5 cents per hour.

Almost immediately after the higher wages became effective the "recession" of 1937-38 set in and railroad net earnings dropped close to the low level of the earlier depression years. The loss in gross revenues coupled with the higher wage scale created a serious financial situation. Late in April 1938, the railroads attempted to reduce wage rates 15%, but the move was strongly resisted by the unions. Direct negotiations and mediation failed. The railroads asked that the dispute be arbitrated, but the unions refused. When the railroads insisted on carrying through the wage reduction, the employees threatened to strike. Then President Roosevelt appointed an emergency fact-finding board which made a report on Oct. 29, 1938, recommending that the wage reduction should not be made. The railroads thereupon withdrew the notice of the proposed wage cut.

On June 10, 1941, the two groups of unions presented new proposals. The operating group asked for a 30% advance in the basic wage, with a minimum increase of \$1.80 per day. The nonoperating group sought an increase of 30 cents per hour and a minimum hourly wage of 70 cents—equivalent to an increase of from 45% to 50%—and in addition asked for an annual 2-week vacation with pay. Again direct negotiations and mediation were ineffective, and an emergency fact-finding board was appointed. Its report of Nov. 5 recommended an increase of 7.5 cents for the operating group and 9 cents per hour for the nonoperating group with a 1-week vacation with pay for the second group.

The railroads were willing to grant the recommended

Notice posted by a New York stationmaster on May 23, 1946, when members of the Railroad Trainmen and Locomotive Engineers Brotherhoods struck for an 18½ cents per hour wage increase

increases, but they were rejected by the unions and a strike was called to begin Dec. 7. This action led to a series of conferences at the White House. Acting on the suggestion of President Roosevelt, and with the consent of both parties, the fact-finding board members resolved themselves into a mediation board and as such worked out an agreement which gave the employees more than the mediators in their former status as a fact-finding board had recommended. The operating group received 9.5 cents per hour (10.6%) and the nonoperating group received 10 cents per hour (15.6%) and a paid vacation ranging from 6 to 9 days, depending on length of service.

In the fall of 1942 the nonoperating unions asked for further increases. Similar action was taken by the operating brotherhoods in Jan. 1943. The nonoperating unions set as their goal an increase of 20 cents per hour with a minimum increase of 70 cents per hour. The operating unions demanded a 30% increase with a minimum advance of \$3 per day. Following unsuccessful negotiation and mediation, the matter was placed in the hands of an emergency fact-finding board whose report in May 1943, recommended a general wage increase of eight cents per hour. This recommendation was accepted by both unions and railroads but it was disapproved as too high by the director of economic stabilization. An impasse developed and a strike was called. The strike was averted by President Roosevelt's action, under his wartime powers, in seizing the railroads and turning them over to the army for operation. In effect it was a "token" seizure. The management was actually lodged in the hands of a small group of railroad presidents who were temporarily commissioned as colonels and reported nominally to an army general. This step having been taken, negotiations were resumed. The president's suggestion that he act as an arbitrator was accepted by both sides, and his award gave the operating employees an increase of 9 cents per hour and an average of 9.4 cents per hour to the nonoperating employees. In addition, the operating men were given an annual vaca-

tion of one week with pay, a privilege earlier awarded to the other group.

The year 1944 was free from wage controversy, but in mid-1945 a new set of demands was presented by both groups. The operating men asked for an increase of \$2.50 per day and favourable changes in certain rules affecting wages and employment. The nonoperators requested 30 cents per hour. Again negotiations broke down and mediation was ineffective. In this case, however, there was inter-union friction. The engineers and trainmen refused to go along with the other 18 unions. In Jan. 1946, the 18 unions agreed to arbitration, the result of which was an award of an increase of 16 cents per hour and certain rule changes favourable to labour. The award was accepted by the 18 unions but was rejected by the engineers and trainmen. These two unions had not been parties to the arbitration. With the rejection went a notice that a strike would be called.

On March 8, 1946, President Truman appointed an emergency fact-finding board which, after hearings and further study, recommended (April 18) for the engineers and trainmen the same increase and rule changes awarded by the arbitration board to and accepted by the other 18 unions. This the engineers and trainmen rejected and a strike call, after one short postponement, went into effect at 4.00 P.M. on May 23. The dispute had previously gone to the White House, and in the conferences there President Truman had suggested as a compromise that the 16-cent increase be made 18.5 cents per hour, the extra 2.5 cents to be in lieu of rules changes, further consideration of which would be deferred 1 year. This compromise had been accepted by the 18 unions but was unacceptable to the engineers and trainmen. On the day preceding the strike the president, under his emergency powers, had seized the railroads and directed the Office of Defense Transportation to take over the operation, but the fact that the railroads were being operated by the government did not deter the engineers and trainmen from striking. Trains could not be operated without them, and a nationwide stoppage of rail transportation became almost instantly complete.

On the following day President Truman, in a radio broadcast to the nation, severely criticized the actions of Presidents Alvanley Johnson and Alexander Whitney of the engineers' and trainmen's unions and stated that he would recommend to congress that steps be taken to draft the strikers and place railroad operation under the army. On the next day he appeared personally before a joint session of congress and made those recommendations which, with others, would drastically curtail the powers of labour leaders to strike against public interest. Yielding to the force of a strong adverse public opinion and to pressure from other unions, the leaders of the engineers and trainmen capitulated. They agreed to accept the compromise suggested by the president; the strike was called off, railroad operation was resumed after a two-day stoppage and federal operation of railroads was immediately terminated.

The average number of U.S. railroad employees was 1,114,663 in 1937. It dropped to 939,171 in 1938 and thereafter increased steadily year by year until it reached 1,420,266 in 1945. In May 1946, it had dropped to 1,306,814.

The average annual compensation of all railroad employees, including overtime and other allowances in addition to straight time, was \$1,781 in 1937, \$1,913 in 1940, \$2,307 in 1942, \$2,727 in 1944 and \$2,718 in 1945. The average rate per hour for straight time, exclusive of over-

time and other allowances, was 70.1 cents in 1937, 74.2 cents in 1940, 83.5 cents in 1942, 93.0 cents in 1944 and 93.3 cents in 1945. The figures for 1946 were influenced by the wage increases late in May.

Regulatory Laws.—In the field of U.S. railroad legislation, the principal developments during the decade were the passage of the Transportation act of 1940 and the extension of the powers of the Interstate Commerce commission over freight forwarders in 1942.

The outstanding features of the 1940 Transportation act were (1) the declaration of a national transportation policy which would give fair and impartial treatment to all modes of transportation; (2) the inclusion of inland and coastal water carriers among the agencies subject to regulation by the Interstate Commerce commission; (3) the revision of the section dealing with consolidation, with provision for voluntary consolidations initiated by the carriers subject to commission approval; (4) repeal of certain land grant rates (reduced rates to the government by railroads which received land grants); (5) enlargement of commission powers in supervision and control in matters of finance and accounts and (6) the creation of a temporary board of investigation and research to determine the relative fitness and economy of the several modes of transportation, to report on the extent and equity of taxation and to determine the degree of public subsidy extended to each mode.

Other legislation included an act which provided a national system of retirement and pensions for railroad employees on a scale higher than that provided by the Social Security act; a signal inspection act which expanded the powers of the Interstate Commerce commission over the adequacy, design, operation and maintenance of railroad signal systems; the Voluntary Adjustment act of 1938 (Chandler act) which, for a limited period, permitted a railroad in financial distress to effect a financial reorganization by direct negotiation with creditors without recourse to receivership or trusteeship; and the Boren bill, which repealed provisions of the several Land Grant acts requiring railroads receiving land grants to carry government freight and personnel at reduced rates.

Anti-Trust Proceedings.—The U.S. department of justice, in Aug. 1944, instituted proceedings against the Association of American Railroads, the Western Association of Railway Executives, certain western railroads and several individuals, including railroad officers and bankers, alleging violation of the Sherman Anti-Trust act in collusion in rate-making, retarding the development of competing forms of transportation and blocking the introduction of new equipment and technical improvements.

The principal objective of the suit was to outlaw the regional rate-making associations of railroad officers, associations which for many years had functioned with the approval of the Interstate Commerce commission. To these associations the individual railroads submitted their rate proposals before they were filed with the regulatory authorities. The associations were effective in preventing ruinous rate wars. In the opinion of the department of justice, the associations restrained free competition and hampered the individual railroads in taking action independent of other railroads, and were therefore illegal. The Bulwinkle bill, which passed the house in Dec. 1945 and was favourably reported by the senate committee, failed to come to vote in the senate. That bill, which would have legalized the associations, subject to supervision by the In-

Railroad marshalling yards in Paris were rendered useless by R.A.F. bombers in 1944, to prevent shipment of German troops or matériel to the Normandy sector after Allied landings on D-day

terstate Commerce commission, was strongly supported by the commission and most of the associations of shippers, but it was just as strongly opposed by the department of justice. Its enactment would have cut the ground from under the anti-trust suit which was still pending at the end of 1946.

In 1940 the anti-trust division of the department of justice instituted proceedings against Pullman incorporated, a holding company. It controlled the Pullman company, which owned and operated Pullman cars under contractual relations with railroads, and the Pullman-Standard Car Manufacturing company, which manufactured and sold passenger and freight cars for railroad use. The principal basis for the suit, which was tried before a federal three-judge expediting court in Philadelphia, was the allegation that the close contractual relationship between the Pullman company and the railroads gave the Pullman-Standard an undue advantage in selling cars to the railroads, and that it was prejudicial to the interests of other car builders. The decision of the court in Nov. 1943, upheld the department of justice and a dissolution was ordered. Pullman incorporated was given the option of disposing of its car-building subsidiary or its operating subsidiary. It chose to go out of operation and to confine its activities to car building. The Pullman cars of the Pullman company and its service facilities were offered to the railroads with the suggestion that the railroads organize a jointly owned operating company to purchase the equipment and take over the organization. In further court proceedings, when the proposed sale came on for approval, other bidders appeared but the court decided that the railroad bid should be accepted. The decision was appealed by the department of justice on the ground that railroad ownership would perpetuate some of the elements of monopoly. The case was still in the hands of the supreme court of the United States at the end of 1946. In the meantime, with court approval, the Pullman company continued to operate, service and maintain the cars pending further court action.

MEDIATION BOARD.)

(W. J. C.)

Great Britain.—The year 1937 was one of continuing recovery from the period of industrial and economic depression of the earlier 1930s, and the four British main line railways (the London Midland and Scottish, the London and North-Eastern, the Great Western and the Southern) together earned 3.43% on their capital. A recession in 1938 owing to the unsettled political situation reduced net earnings to 2.61%. The threat of possible war induced the minister of transport to appoint a Railway Executive committee (R.E.C.) in Sept. 1938 to act as an advisory body in the event of a national emergency. In Sept. 1939 this committee, in accordance with the Railway Control order, became the channel of communication between the minister of transport and the railways.

The R.E.C. had accomplished much preparatory work in the intervening 12 months, including plans for the evacuation of the civil population of London, requiring 4,300 trains to carry 1,430,000, and the constitution of its 16 subsidiary committees, corresponding to the committees of the railway clearing house in peacetime, drawn from operating superintendents, civil engineers, accountants, etc. Thus, when the minister of transport took over the railways by an order in council under the Emergency Powers Defense act (Aug. 1939), all was prepared to handle the essential priority war traffics. Further, the R.E.C. was to carry on as long as the control of the railways by the government continued, which was still the case in 1946.

On the financial side, an agreement was reached in 1940 by which the government guaranteed to the four railways and the London Passenger Transport board £40,000,000 as the guaranteed net revenue in the following proportions: L.M.S. 34%; L.N.E. 23%; G.W.R. 16%; S.R. 16%; L.P.T.B. 11%. This payment derived from the receipts and expenses of the controlled undertakings pooled as from Sept. 1, 1939. Of any further balance of net revenues in the pool, the balance up to £43,500,000 was to be paid to the controlled undertakings, any further balance up to £56,000,000 to be shared between them and the govern-

Tactical bombing of German rail communications along the German line of retreat supported Allied advances into western Germany during the early months of 1945. Here a railroad track at Dernau is shown after it was blasted off the ground

Reconstruction work on the French railroads, a critical factor in postwar industrial recovery in France

ment; any excess more than that figure was to be retained by the government. It was also agreed that railway charges would be raised to compensate for any rise in costs. As from May 1, 1940, on the recommendation of the R.E.C., these charges were indeed increased by 10%, applying also to rail fares of the L.P.T.B. Later the road fares of the latter were suitably adjusted. On Dec. 1, 1940, this 10% rise was increased to 16%.

Changed conditions in 1941, including the government's desire to prevent inflation and its policy in regard to the compensation for war damage in the case of public utilities, caused the government to claim a revision of the first control agreement and a second one operated after 1941. The latter granted the four railways and the L.P.T.B. together a guaranteed annual rental of £43,000,000, the exchequer retaining any balance of net receipts left in the so-called pool. In effect, this left the return on railway capital proper after 1940 on the 3.48% level. The government, by retaining all the surplus, had by the close of 1945 accumulated a profit of about £197,600,000. Provision was made for renewals of track, etc., deferred during the war years, by the formation of trust funds for each railway. Sums so reserved totalled £116,300,000 at the end of 1945. The year 1946 marked a turning point with the rapid fall in war traffic and in revenue, with the result that as from July 1946 the government, to offset a major reduction in the pool's net revenue, raised freight rates to 25% and passenger fares to 33% above prewar, with certain lower exceptions such as "season" and "workmen's" tickets.

On the traffic side, the British company-owned railways were called upon to face, in 1940-45, a series of crises and strains which they were in excellent condition to withstand. First came the extra load of mobilization of the armed forces and the civil evacuation from threatened areas in 1939. For the latter, more than 3,800 trains were run, exclusive of empties, and they carried more than 1,334,000 evacuees in Sept. 1939. During the six years 1940-45 a further 1,800 trains were run for this purpose, carrying

more than 1,000,000 passengers. Many others travelled by ordinary trains, though civil passenger services during the war years were cut by about 30% to make way for the heavy war traffic of troops and freight. The original dispatch of the British expeditionary force to France required the running of 261 special trains to Southampton alone in 27 days (Sept.-Oct. 1939), while the small expeditionary force to Norway in April 1940 demanded 202 specials. The evacuation from Dunkirk, for which no prearranged plans could be made, required 620 specials from the channel ports carrying 319,000 troops within a few days.

The arrival of U.S. forces in Britain, beginning in the summer of 1942, placed a further load on the railways, while later that year the dispatch of Allied forces to North Africa required 440 troop specials, 680 freight specials and 15,000 other wagons to be worked to the ports. To mount the "Overlord" landing in France on June 6, 1944, 80 troop and motor vehicle trains were scheduled daily, and during one week in June 1944, 271 trains conveyed 99,000 troops; from June 6, 1944 to May 7, 1945 (D-day to V-E day) the total number of specials worked for this purpose was 4,794. The number of special trains operated from Sept. 1939 to Aug. 11, 1945, on behalf of the government, counted separately for each railway, was 258,624 passenger trains and 279,935 freight trains, giving a grand total of 538,559.

This immense additional military traffic and the shortage of skilled staff provided many difficult problems. As distinct from the United States, the U.S.S.R., Germany and Belgium for example, where there were great increases, the British railway staff, numbering 588,517 in March 1939, rose only to 622,369 in March 1945. Of these, more than 90,000 were women, against only 25,000 in 1939. The locomotive shortage at times became critical, since the railways' construction and repair shops were largely allocated to war purposes. There were about 19,500 locomotives in 1939, and during the war about 240 steam or diesel units were handed over to the government. By Aug. 1945, the percentage of locomotives under or awaiting repair had

risen to 16.3, but the loan of about 850 British- and U.S.-built "austerity" type freight engines from 1943 onwards, until they were withdrawn for service abroad, materially eased the strain at a crucial period.

The changed direction of the flow of traffic, partly caused by the diversion of ocean vessels to western ports and the transfer of coal and other traffic from coastal vessels to the railways, compelled the widening of certain double-track main lines to four tracks, as between Cheltenham and Gloucester, the building of new marshalling facilities, as at Oxford and the construction of short cut-offs to provide alternative routes. Certain single-line branches were widened or provided with additional passing places, as between Didcot and Winchester. To ease the wagon situation, the 585,000 privately owned wagons were added to the common pool of the 650,000 owned by the railways. By more rapid loading and unloading, together with heavier loading per wagon, the war traffic offering was handled successfully, though ordinary civil traffic was somewhat reduced by zoning schemes under which the distribution of certain commodities was confined to the areas of production. In 1943, the peak year for freight, more than 45,000,000 wagons were dispatched. Passenger traffic continued to increase in 1944, with 1,276,000,000 journeys, reaching its peak in 1945. While much preparatory work had been done in air raid precautions after 1937 and nearly £1,500,000 had been spent in accumulating emergency stores for repair work, the first serious damage from air attack came in June 1940. By March 28, 1945 (the last instance), reported incidents of damage and delay by air raids totalled 9,239, of which 1,595 affected traffic facilities for not more than 24 hours. The worst periods were Sept. 1940 to April 1941 and June 1944 to Aug. 1944, when the flying bomb attacks took place on southeastern England. Incidents affecting the railways and the L.P.T.B. lines resulted in 900 fatal casualties and injuries to 4,450, of which about one-third were on the S.R. Altogether nearly 400 railwaymen were killed. The "black-out" at stations, yards and in trains, especially during the long winter nights, created operating difficulties and caused delays, but the safety record was remarkable, with an annual average of only 30 passengers killed and 42 seriously injured in train accidents for the six-year period 1940-45.

Despite all war traffic preoccupations, considerable long-range planning work was undertaken, aiming at improved design of passenger cars and steam locomotives, electrification, the increase of diesel traction and the extended use of metals, including lightweight materials for rolling stock. Several new types of locomotives were placed in service. Mention may be made of the "merchant navy" and "west country" type "Pacific" (4-6-2) classes for the S.R. and new 4-6-0 classes on the L.N.E.R. and the G.W.R. In 1946 the G.W.R. converted some of its steam locomotives from coal to oil firing, and the S.R. electrified further sections on the third rail system in the early war years. Progress was made in linking up the L.P.T.B. tube lines with those of the main line companies, but the large-scale plan for improvements of this character in the London area had to be shelved until 1946. In 1945 some of the cross-channel services were operated by the railway steamers, released from government requisition. Mechanized handling was extended at freight stations, as at Birmingham, and in road cartage. The number of containers increased greatly.

France.—In 1937, the four French company-operated railways with the state-owned and -operated, Etat (ex Ouest) and the Alsace-Lorraine railways were amalgamated into a

single French national railways system (Société Nationale des Chemins de Fer Français). The S.N.C.F. came into being on Jan. 1, 1938, and the coincidence of consolidation and government operation provided a major problem of organization. In fact, the reorganization of staff appointments and technical standardization had not been completed when war broke out in 1939, though the broad outlines of the new system had been laid down. Thus the Nord, the Est (with the Alsace-Lorraine), Paris-Lyons-Méditerranée, the Paris-Orléans-Midi and the Etat railways became respectively the Nord, Est, Sud-Est, Sud-Ouest and Ouest *régions* of the new S.N.C.F. Such a complete reorganization of a large country's railway system was almost without precedent, but, in spite of this period of unsettlement, technical progress was continued, and the conversion to electric traction of the Tours-Bordeaux main line was completed early in 1939, thus giving an electrified line throughout from Paris to the Spanish frontier at Hendaye. Similar conversion of the Mountauban-Brive section of the alternative main line to the Spanish frontier at Cerbère (for Barcelona) was begun but, owing to the war, was not completed until 1943. During World War II, plans were prepared for the conversion of the heavy traffic artery from Paris to Lyons, but little work, other than preparatory, had been begun by 1946. The year 1939 had witnessed the preparation of designs for standard locomotive types, passenger cars and wagons, but few units could be produced before 1946.

The invasion of France in May 1940, leading to partial occupation which finally extended to the whole country in Nov. 1942, caused immense damage to railway property, especially bridges. Not until 1943 were all the lines fully re-established, but by that time large-scale damage was

The Golden Arrow express arriving at Paris early in 1946 after completing the first scheduled postwar run between London-Calais and Paris

being caused by the Allied air attacks in preparation for the landing in Normandy in June 1944. These attacks before and after the landing, coupled with destruction caused by the retreating Germans, sabotage by French partisans to help the Allies and damage by the land fighting itself, created immense losses to the S.N.C.F., added to which was the steady removal of equipment from France for use in Germany, and German-occupied territories. When Paris was liberated in Aug. 1944, there was hardly any French main line capable of carrying traffic for more than a few isolated miles. Indeed, for some time Paris itself was cut off from the rest of the country by rail. The freezing and sterilization for a few vital weeks of the S.N.C.F. system was a major factor in the rapid liberation of France, but the material losses were heavy, especially at such key centres as Tours, Amiens, Orléans, Cambrai, Aulnoye, Le Mans and on the outskirts of Paris. Partly on that account, Paris was rendered indefensible and emerged almost unscathed.

Extent of damage to the French railways, Aug. 1944

Permanent way:	
Out of commission	11,185 mi. (out of 24,233 mi.)
Requiring reconstruction	1,988 mi.
Destroyed switches	10,000 pairs
Buildings, etc.:	
Large stations badly damaged	115 (out of 300)
Signal cabins destroyed	571
Large classification yards badly damaged	24 (out of 40)
Large locomotive depots badly damaged	74 (out of 130)
Bridges, viaducts, etc., destroyed or badly damaged	2,400
Tunnels obstructed	43

The energy with which the reconstruction work was afterward carried out reflected great credit on the French railways.

Equipment in 1938 included 16,000 steam locomotives; in Aug. 1944, only 3,000 were available for service. But by Jan. 1946 this figure had risen to more than 8,700. In 1946 large numbers built to French design in the U.S. were arriving in France and, together with an energetic repair program, helped overcome the critical shortage of power. In 1938 France had 478,000 freight wagons. By Jan. 1945 only 152,000 were serviceable, though there were many German, Hungarian, Belgian, Italian and other wagons in circulation. By the end of 1946 there were about 300,000 available and wagon loadings per week approached the prewar figure. Shortage of coal and deficiency in vital materials, such as ties and steel, delayed reconstruction, but by July 1946 only one main line remained cut through destruction by the Germans in Aug. 1944 of the large viaduct at Nogent-sur-Marne. Juvisy, Longueau and Tours classification yards were at work again, and passenger services had been rapidly re-established, though naturally not attaining the 1938 level in speed or frequency; nor were they entirely sufficient for the nation's needs. Of the 30,000 passenger cars of 1938, only 17,500 were left in May 1946.

Belgium.—Belgium's main railway network had long been government-owned and operated. As a solution to the financial difficulties following World War I, when the Belgian railway system suffered grievous losses, the system was reorganized as the Belgian National Railways company (Société Nationale des Chemins de Fer Belges). With the exceptions of (a) the light railway system, mainly narrow gauge, known as the *vicinaux*, (b) certain local lines such as the Malines-Terneuzen, later taken over, and (c) the Nord-Belge (affiliated with the Nord railway of France), the S.N.C.B. embraced the whole system. The lease of the Nord-Belge terminated during World War II, and its property and assets became part of the S.N.C.B. The German invasion of 1940 caused great damage, especially in the de-

struction of bridges, but by 1941–42 repairs were complete and, though much equipment had been removed to Germany, the S.N.C.B. was working normally. Though the port of Antwerp was practically idle, internal and transit traffic to France, to satisfy the needs of the occupying forces, was heavy. Sabotage grew during 1942–43, and Allied air attacks increased, becoming sufficiently strong to freeze railway movements on the main lines leading to France, before June 1944. As the Germans retreated, the Belgian railways suffered further losses through air attack, land battles and German destruction. Thus, after liberation only 1,944 mi. were operable out of a total of 3,238. In all, about 30 sections of line were blocked by destroyed bridges or other obstructions.

Allied commanders paid tribute to the fine reconstruction achievements of the Belgian railway staff, but the ordeal was not over, since flying bombs were directed on to Antwerp, Liège, etc. The Ardennes battle (Dec. 1944) did major damage to lines east of the Meuse. As a consequence, in Jan. 1945, 466 bridges required reconstruction, but by 1946 this figure had fallen to 44, though many repairs were of a temporary character. In 1940, S.N.C.B. locomotives had numbered 3,414 and by 1944 only 2,509 remained; however, by 1946 the number had increased to 2,743, and a further 300 were expected that year from the orders placed in the U.S. and Canada. Belgian shops had a further 100 on order. Passenger cars numbered 6,382 in 1940; 3,682 in 1944 and 4,335 by 1946. For months in 1945 the wagon situation was critical, the 1940 stock of 99,000 having fallen by then to 53,700. This loss, largely to Germany, held up the movement of coal and other vital traffic.

Belgian postwar reconstruction was notably rapid. Great efforts were made to achieve financial stability. Both fares and freight rates were increased several times, thus offsetting the devaluation of the franc, but it was inevitable that for a year or two there would be financial deficits. Further electrification was planned and the workshops of Malines and Louvain, largely destroyed, were rebuilt on the most modern lines. Belgium by 1946 had re-established most of its international traffic services and was still carrying much military leave and supplies transport for the Allied forces occupying Germany. As in many other countries, shortage of fuel limited train mileage.

The Netherlands.—Prior to the invasion by Germany in 1940, the Netherlands railway system belonged to a government-owned company. Several sections operated with electric multiple-unit type equipment for passenger services using overhead catenary feed, as for instance from Dordrecht to Rotterdam, Amsterdam, Eindhoven and Utrecht, while there were many diesel streamlined trains at work, running to Maastricht and Groningen. Except for damage to some of the great bridges over the Rhine and other rivers, little damage was suffered in 1940, and Allied air attacks never became as serious as they did in France and Belgium in 1943–44. The tragedy of the Netherlands railways started with the heroic strike of the Dutch railwaymen in the fall of 1944 when they hoped that the Allied offensive at Arnhem would bring liberation to Holland. The offensive failed and the Germans in revenge for the strike took whatever they could of the whole Netherlands railway's fixed and movable equipment, sending the electric and diesel train sets to Bremen and elsewhere, removing the steam locomotives, etc. and even the catenary structures, ostensibly to loot the copper. What could not be removed was destroyed.

There was probably no parallel in railway history to the Dutch experience; from Sept. 17, 1944, to May 5, 1945, Holland's railways and industry lay paralyzed. Figures told a fine story of reconstruction. Mileage operated (Sept. 1944) was 1,974, of which 62% was destroyed or removed by May 1945; by June 1946, 91% had been restored. Of 354 mi. of electrified lines, 92% was destroyed but by June 1946 electric trains were again operating over 115 mi. In Sept. 1944 daily passenger train mileage was 38,562, freight train mileage 24,375; in May 1945 comparative figures were 1,183 and 1,313 respectively, but by June 1946, 68% and 85% respectively of the Sept. 1944 figures had been achieved.

Germany.—In 1937 the German railway system, with the exception of a large number of purely local lines, often narrow gauge, was owned and operated by the Reichsbahn (national railways). In fact the director-general, Dr. Julius Dorpmueller, was also minister of transport. In 1938 the Reichsbahn absorbed the Austrian federal railways and later the lines in the Sudetenland; the 1938 figures of size were:

Route mileage	41,882	Track mileage	92,458
Steam locomotives	21,838	Electric locos	571
Passenger train cars . . .	81,176	Freight cars	591,658

When adjacent countries were overrun (Poland, Denmark, Norway, Holland, Belgium, France, Yugoslavia, Greece and large areas of the U.S.S.R.) the Reichsbahn had to provide a control staff, as also in Hungary, Rumania, Bulgaria and Italy.

The number of Reichsbahn employees, which stood at about 900,000 in 1939, thus rose to more than 1,600,000 in 1944.

The German war potential rested on the full functioning of its rail communications. Despite losses and damage in the U.S.S.R. and by air attack, the Reichsbahn locomotive position remained numerically strong, reaching a maximum of nearly 38,000 in mid-1944. Nevertheless, air attacks stopped the fluidity of traffic, thus preventing the distribution of such essentials as locomotive coal. It was calculated that by the spring of 1945 about 10,000 locomotives were unserviceable; indeed, by then the Reichsbahn was in a state of disintegration. After the close of hostilities in Europe the Reichsbahn of 1937 was virtually split into four systems, one for each of the four zones of occupation. Reconstruction proved slow and difficult, but in the British zone, out of 7,887 route mi. approximately 7,450 were working again in June 1946, against only 652 mi. a year earlier. The first important revival of international train services through Germany was the inauguration of the Nord express from Calais and Paris to Copenhagen and Stockholm in the spring of 1946.

Italy.—The Italian state railways were largely electrified in 1937 but electrification, which had been energetically pushed forward, was brought to a stop in 1940 when Italy entered the war. Italy later became a battleground from Sicily to Trieste, the Brenner pass and Modane, and although the Allied armies advancing northwards were compelled to reconstruct bridges and classification yards and to restore main line facilities from Reggio and Bari via Naples and Rome to Florence, Bologna and the northern cities, the Italian state railways system was largely in a derelict condition in May 1945. At one period all the bridges over the Po had been destroyed. Reconstruction can best be demonstrated by the fact that electric traction was resumed between Reggio di Calabria and Milan (820 mi.). Electrification of the Venice-Padua-Milan, the Domo-

dossola-Milan-Turin and the Padua-Bologna main lines were scheduled for completion in 1947. In all, 2,400 track mi. and 490 bridges and viaducts had to be reconstructed.

Austria.—In 1945 the Austrian federal railways were again separated from the Reichsbahn, though they were until 1946 operated under the quadripartite control of the occupying Allied forces. Further electrification to ease the fuel situation was planned and the Attnang-Puchheim to Linz and the Spittal to Villach sections were to be given priority.

Central Europe and the Balkans.—The damage to the Czechoslovak state railways, which had been separated into two systems during the German occupation—the Bohemian-Moravian protectorate system and the Slovak state railways—was mainly confined to loss of rolling stock, though war damage in Slovakia was heavy. In 1945 the prewar unified administration was re-established except for the lines in the most easterly section of the country which Czechoslovakia lost through a change in the frontiers.

The Hungarian and Rumanian state railways were called upon during World War II to handle an immense oil traffic from the Ploesti fields to Germany. This traffic, coupled with large-scale troop movements to the southern Russian front, strained the limited resources. War damage was heavy as also in Yugoslavia and in Greece, where practically no rolling stock was left in serviceable condition when liberation came. There were many major engineering features on the Balkan railways, a large proportion of which were destroyed, as on the lines between Athens and Salonika. Hence, traffic was still interrupted at many places at the close of 1946. Locomotives built in the U.S. and Great Britain were allocated to Yugoslavia and Greece.

Spain.—In 1937 there were four major railway systems in Spain, the Norte, the Madrid-Zaragoza-Alicante, and the government-owned Western and Andalusian systems, together with some local lines. All these were consolidated into one large government-owned system, the Red Nacional de los Ferrocarriles Españoles. Its primary task was the rehabilitation and reconstruction of the network after the disastrous period of civil strife, and steady progress was achieved. The first phase of electrification of the ex-Norte main lines stretching northwards from Madrid was completed.

Scandinavia.—Few railway systems made more consistent progress over the period 1937-46 than did the Swedish state railways. Two features stood out in their policy: first, the steady extension of electrified mileage; second, the taking over by the state of the various small company-owned railways. Thus the state railways grew to a route length of 8,216 mi. and nearly all the main traffic arteries had been electrified by 1945. Technical progress was also striking, exemplified in new electric locomotives and in the mechanized method of track renewal. Coal supply difficulties enforced the use of wood fuel on locomotives for a period and also prompted the energetic prosecution of the electrification program.

The Danish state railways after 1940 were prevented from extending suburban electrification in the Copenhagen area and during the war lack of oil fuel set back their dieselization program. The train-ferry services over the Great Belt suffered much during the unusually heavy winters of 1940 and 1941 and several of the vessels were damaged by mines. In 1946 prewar projects were resumed with vigour. In Norway the state railway system was extended for military purposes up the west coast towards Narvik, but the future of this military line remained problematical.

Switzerland.—The technical and managerial progress in many spheres which the Swiss federal railways achieved during 1937–46 was remarkable, whether assessed in terms of station design, electrification, track improvements, public relations or internal organization. Under difficult conditions the plans for complete electrification of all lines were steadily pursued until, by 1946, 95% of traffic was being hauled electrically. Swiss designs of lightweight passenger cars were structurally as remarkable as the designs in the U.S., while in regard to electric locomotive designs, the Swiss federal, together with its neighbour, the Bern-Lötschberg-Simplon, probably shared with the Swedish state railways the pre-eminent position in Europe. In 1946 a remarkable new ten-year program of improvements was being pursued.

U.S.S.R.—No reliable information of any kind became public about the railway system of this country, nor on the lines in soviet-occupied zones.

Asia.—In Asia the decade 1937–46 witnessed the construction of important new railway mileage. In 1940 the first passenger train left Baghdad for the through run to Haidar-Pasha, linking with the standard gauge, 4-ft. 8½-in. railways of Iraq, Syria and Turkey. By 1942 the Palestine and Turkish railways were linked by a standard gauge line through Beirut. Thus it became physically possible to operate through trains from the eastern side of the Bosphorus to Cairo and Alexandria. A vital link in the Allied war effort was the route in Iran from Bandar Shahpur to Bandar Shah on the Caspian. Operation over this line was immensely difficult owing to grades, climatic conditions and fuel and water problems, but by July 1944 the line was handling 10,000 tons a day, a magnificent achievement of U.S., British and Russian co-operation.

In India the policy of the central government in taking over the management of the company-operated railways continued throughout 1937–46. By 1946, with the exception of the lines owned and operated by certain of the Indian states, the government of India owned all the important mileage. Farther east, World War II left Burmese and Malayan railways in a disastrous condition, though the Japanese during their temporary occupation had, by forced labour, constructed certain links joining the Siam state railways with those of Malaya and Burma. Rehabilitation continued rapidly in this area. As a consequence of the defeat of Japan the South Manchurian system fell under joint Russo-Chinese control by the terms of the China-Changchun Railway agreement. By April 1946 the Japanese government railways' mileage open to traffic totalled 13,022 mi., involving 4,117 stations.

Africa.—Railway developments in Africa during 1937–46 were primarily aimed at increasing operating capacity. In South Africa the South African Railways and Harbours administration, which also owned and operated the harbours and air services, grew to be one of the largest railway organizations in the world, with a route mileage of more than 13,300. Improved signalling and new deviations to ease grades and curvature helped to overcome the difficulties which arose from inability to obtain new motive power or equipment until 1944–46. Large-scale electrification plans had to be temporarily postponed. The situation eased with the arrival of new locomotives; traffic in 1946 was still running at a very high level. South African railways workshops carried out large-scale orders for war stores. Garratt locomotives proved highly successful, not only in South Africa, but also on the adjacent Rhodesian railways and in Kenya-Uganda as they operated over comparatively light rails and severe curvature.

In 1941–42, some progress was made with the construc-

tion of the long projected Trans-Sahara line. Development of the Kenadsa coalfields thereby became possible, but little progress was reported after 1943, when the great trunk route from Casablanca to Tunis was being used to handle war traffic far above anything previously envisaged on the Moroccan, Algerian and Tunisian railways; many locomotives built in the U.S. were in use, and the Egyptian state railways were also assisted in the handling of peak traffic by the arrival of locomotives built for the Allied war departments. The Djibouti-Addis Ababa railway was returned to its French ownership in 1946.

Canada.—Canada's two great railway systems, the Canadian National railway (23,535 route mi.) and the Canadian Pacific railway (17,037 route mi.) were faced with major problems during the war period in handling huge passenger and freight traffic. Fortunately in 1939 both properties were in a high state of efficiency and maintenance, but few envisaged then that the work to be done in 1943–45 would approach, if measured in passenger-miles, three times the 1939 figure, and in ton-miles more than double. These increases demonstrated the inherent power of well-managed and well-equipped railways. They showed too, that the financial difficulties of the Canadian railways so frequently referred to before World War II, were primarily due to lack of traffic density.

While their main construction and repair shops were largely devoted to the production of war stores, the Canadian lines were hard pressed; but improved signalling facilities, such as the centralized traffic control installation on the Moncton-Truro section and the extension of automatic block signals on much of the C.P.R. mileage, assisted the satisfactory handling of war traffic between the Atlantic and the Pacific coasts. Almost unique to Canada was the linking of the railways with the development of air services, and the C.N.R.'s affiliate, the Trans-Canada Air Lines, with the latter's regular service across the Atlantic as well as from coast to coast, was a landmark in railway history. The C.P.R. similarly welded many small air lines into one entity, the Canadian Pacific Air Lines, radiating out from the Trans-Canada east to west artery, and thus reaching far into the northland.

Mexico.—The railway position in Mexico for many years before 1937 had been unsatisfactory and the national railways had suffered from repeated changes in organization and executive personnel. At one period management lay in the hands of the workers themselves, but this proved far from successful. With expert technical advice obtained from the U.S. a large-scale rehabilitation program was inaugurated in 1941 and continued till 1946. A new board of management under the presidency of the under secretary of the Mexican government achieved consistent progress. By 1945 fast freight through trains operated between Mexico City and several interchange points on the U.S. railroads; the roadbed had been strengthened with heavier rail and much added ballast, and a large number of diesel locomotives were already in service, with further similar units due for delivery in 1946.

South America.—Railway construction continued spasmodically during 1937–46 in South America, but the main problems concerned finance and fuel. The latter proved most intractable, even maize being used to keep trains operating in Argentina. Successive shortages in coal and oil forced repeated conversions from one fuel to another in the case of steam locomotives, and in Brazil electrification was largely adopted as a solution. Inadequate return on capital impeded the financing of renewals, thus

strengthening the tendency of governments to take over certain lines, for example the Arica-Tacna in 1942. Largely cut off during World War II from sources of supply in the U.S. and Europe, the railways had to adopt ingenious methods for meeting recurrent shortages in important materials. The labour situation was not easy.

Progress in physical extension was made on the Salta line, linking Argentina to Chile at Paso de Socompa, 221 mi. from Antofagasta, scheduled for completion in 1947. In 1943, agreement was reached to reconstruct the Transandinine railway, out of service since 1934. Brazil planned the electrification of the Sorocabana railway and the Central do Brasil, while the Paulista line planned to convert its line to Bauru, and the São Paulo its section to Jundiahy. Further suburban electrification in the Rio de Janeiro area was under consideration by the Leopoldina. In 1946 the international railway bridge was opened between Brazil and Argentina at Uruguayana-Paso de los Libres.

Australia.—The entry of Japan into World War II affected the whole Australian railway situation. Front line conditions faced the section of the commonwealth railways in the Northern Territory, while northern Queensland temporarily became a war zone. Locomotives had to be loaned from one state administration to another or to the Commonwealth. The difficulties arising from the variation in gauges, such as the 3-ft.-6-in. gauge in Queensland, Western Australia, Tasmania and parts of the South Australian and commonwealth railways, the 4-ft.-8½-in. gauge in New South Wales and on certain commonwealth lines, and the 5-ft.-3-in. gauge in Victoria and South Australia, drew attention once more to the desirability of a vast gauge standardization project. The design of this scheme, of great strategic and economic importance, was allocated to Sir Harold Clapp. The plan he put forward in 1945 provided for the modernization of the various Australian state systems. Divided into three proposals estimated to cost £A77,000,000 (\$247,000,000) in all, the main features embraced: a new standard gauge line Fremantle-Perth to Kalgoorlie, conversion of the 5-ft.-3-in. mileage in Victoria and in South Australia to 4 ft. 8½ in. and conversion of some 3-ft.-6-in. mileage to 4 ft. 8½ in. in the latter state; conversion to standard gauge of the Port Pirie-Broken Hill route; construction of a new 4-ft.-8½-in. standard gauge line from the New South Wales border to Northern Queensland and involving the conversion of considerable 3-ft.-6-in. gauge mileage in Queensland; and conversion of the 3-ft.-6-in. gauge Birdum-Darwin section of the commonwealth railways in Northern Territory. The scheme was a long-term project, and certain amendments undoubtedly would be agreed to in view of the conflicting interests of the individual state administrations. On several state systems the heavy war traffic converted financial deficits, after the payment of fixed charges, into healthy surpluses, as, for instance, £A775,000 (\$2,487,000) in New South Wales in 1943, but rising wages together with the difficulties of replacing rolling stock and motive power made the immediate prospects more sombre. In New South Wales the opening to traffic of the new bridge over the Hawkesbury river in 1946, a very difficult engineering feat and long under construction, was an event worthy of record.

New Zealand.—The situation of the New Zealand government railways was comparable with that in Australia. Though the war zone remained more distant, the increase of traffic on a system less developed from the viewpoint of

traffic density provided its own special problems. By efficient management all demands were met satisfactorily, but inability to obtain new locomotives long on order and shortage of fuel, a difficulty which faced the Australian railways also, made operation complex. The New Zealand transport position benefited substantially from the extent to which rail and road co-ordination had been achieved in the immediate prewar period, and important savings were obtained through the elimination of mixed trains. Large-scale plans for widenings, station improvements and further electrification were held up during the war, but considerable progress was achieved in linking up previously isolated sections with the main line systems in the North and South islands. Ralston, James Layton

Ralston (1881–), Canadian statesman, was born Sept. 27, 1881, at Amherst, N.S. A graduate of Dalhousie law school, he was called to the bar in 1903 and practised law in Nova Scotia. In 1916 he went to France as a major of a Canadian infantry battalion, which he commanded from April 1918 until its demobilization in June 1919. Awarded the distinguished service order with bar, he was made a Companion of St. Michael and St. George and was twice mentioned in dispatches. In 1924 he was promoted to the rank of colonel. He accepted the portfolio of minister of national defense in the federal cabinet in Oct. 1926 and was elected to the house of commons by acclamation the next month. In 1930 he was a delegate to the London naval conference and was again elected member of parliament from Nova Scotia in the elections of that year. With the defeat of the Liberal party in Aug. 1930 he resigned and returned to private practice at Montreal.

On Sept. 6, 1939, he was appointed finance minister in the Mackenzie King cabinet and on Jan. 2, 1940, he was elected by acclamation to the house of commons as a Liberal member for Prince Edward Island. In June 1940, he took over the portfolio of minister of defense, left vacant by the death of Norman McLeod Rogers. Ralston's resignation from the cabinet was announced Nov. 2, 1944. It was understood that the minister of defense quit in protest against the government's refusal to compel military conscripts to serve overseas.

Ramsay, Sir Bertram Home

Sir Bertram Ramsay (1883-1945), British naval officer, was born at Coldstream, Berwick. Son of an army officer,

he broke with the family tradition and joined the royal navy at the age of 15, later studying at the British Naval Staff college. He commanded the celebrated Dover patrol during World War I. In the peaceful interim between the two World Wars, he alternated his assignments on the staffs of the Naval War college (1927-29) and the Imperial Defence college (1931-33) with periods of active duty. He retired in 1938 with the rank of vice admiral, but returned to active duty at the outbreak of World War II. He was in charge of naval operations during the evacuation of British armies from Dunkirk, May-June 1940, and was made a knight commander of the Order of the British Empire in 1943, in recognition of his part in that operation.

Sir Bertram was naval commander in chief of the Anglo-U.S. expedition that landed in North Africa, Nov. 8, 1942, helped plan and direct the Allied landings in Sicily and Italy and was commander in chief of the Allied navies that supported the invasion of France in June 1944. He was killed Jan. 2, 1945, when his plane crashed near Paris, France.

Rationing

Consumer rationing and price control were used by most nations of the world during the years of World War II. With the major part of the world's productive effort going to support the war, these controls were used to provide a measure of economic stability and to secure fair distribution of scarce, essential goods.

In all belligerent, and in many neutral countries, the diversion of machinery and materials to war production created shortages of most consumer goods. At the same time, rising employment and competition for labour swelled the national income, resulting in increased demand for the very goods which were becoming more scarce.

The more complete the channelling of resources into war uses, the wider became this gap between demand for consumer goods and the supply. Under such circumstances, plans limiting consumption and assuring fair distribution of essential goods to all consumers were necessary for successful prosecution of the war. Civilians had to be fed, clothed and housed, if war production was to be maintained and increased. Transportation had to be provided, both for war jobs and for essential civilian activities. Civilian morale had to be maintained at the highest possible levels. These things could be accomplished only if living essentials were available and equitably distributed. Rationing introduced the criteria of need and fairness in place of the usual criterion of ability to pay. It reduced consumption of goods in short supply and prevented some from obtaining more than their fair share. Other measures, such as compulsory or voluntary savings plans, increased taxes and curtailment of consumer credit helped reduce money demand for all goods.

Many governments found it necessary not only to make supplies available to meet ration demand, but to make them available at prices consumers could afford to pay. Government purchase, with resale at lower than open market prices, and subsidies helped achieve this goal. In

the United Kingdom, Sweden and Switzerland, all individuals were assured their rations even though they could not pay the full purchase price.

Administration.—To ration effectively, it was necessary not only that total supplies be adequate to meet minimum requirements, but that rationed goods be available wherever consumers had ration currency to spend. The central rationing authority usually had control of the supply of rationed goods and directed distribution as nearly as possible to match the "ration demand" in each locality. Dealers were registered and inventories were limited with the objective of spreading supplies to all areas and all dealers. Allowable inventories were determined by the ration demand—either by the number of consumers registered with a particular dealer, or by the amount of ration currency consumers spent with each dealer during a given period.

While fair distribution required that rationed goods be available when and where consumers had ration stamps to spend, unforeseen shortages, transportation difficulties, or mistakes in distribution planning sometimes upset ration schemes, thus leaving some consumers without their share of rationed goods. No ration plan worked perfectly, and miscalculations and mistakes were frequent in the early stages of most ration programs in almost every country.

While a central authority devised the ration plan to be used, set the ration level for the "normal consumer," and established criteria under which differential rations would be provided to meet certain kinds of individual requirements, many determinations were necessarily left to local authorities. In the United States, local ration boards determined how much gasoline each automobile owner could use. In most countries local authorities passed on individual eligibility for differential food rations.

Registration.—Consumer rationing was usually preceded by a consumer registration for the purpose of determining eligibility of each individual and for placing in his hands an initial supply of ration stamps or coupons. Once a supply of ration currency of different kinds was distributed, additional rationing programs could be placed in effect without prior notice to the public.

The initial registration for rationing in the United Kingdom was carried out in Sept. 1939, but rationing did not begin until Jan. 8, 1940. Germany had prepared so well in advance of the war that food rationing began there almost immediately after hostilities began. In the United States, automobile tire sales were frozen immediately after Pearl Harbor was attacked, and rationing began Jan. 5, 1942, through individual determinations of local ration boards. The first general consumer registration in the United States, which preceded sugar rationing, did not take place until May 4-7, 1942, since ration planning was begun only after the United States entered the war.

Methods of Rationing.—Three basic methods of consumer rationing were employed during and after World War II. These were *unit* or *specific* rationing, *point* rationing, and *certificate* or *purchase permit* rationing. Each placed in the hands of consumers "ration currency" in the form of stamps or coupons, tickets, certificates or purchase permits.

Unit rationing was generally used to distribute specific quantities of single commodities like sugar, shoes or gasoline, or two or more substitutable commodities, like margarine and cooking fats. It was used for all foods rationed in Germany and in German-occupied Europe, where the allocation of each consumer's share of each

Food rationing to insure a just distribution of scarce foodstuffs among U.S. consumers during World War II became effective in 1942. Carried out mainly through the ration book system, it was often made more equitable by voluntary efforts of retail dealers, as illustrated in this picture

group of foods was determined by rationing authorities, little choice being left the consumer. The plan was also adapted to ration commodities needed in different amounts by different individuals. For example, in the United States, unit rationing provided all consumers who had automobiles with the same basic gasoline ration, and gave additional quantities to certain consumers on the basis of their transportation requirements.

Point rationing's essential feature was that it permitted the consumer to select any item he wished from items rationed under the same program. In Britain, several foods not wanted alike by all consumers were rationed under a single point program. This included canned meats and fish, canned fruits and vegetables, dried fruits, beans and peas, condensed milk, breakfast cereals, biscuits and preserves, jams and syrups. Each commodity was assigned a point value and the consumer spent his points for the foods he preferred. A separate "personal points program" provided equal points to all persons for obtaining chocolates, confections and other sweets. In Britain, on the continent of Europe, in Australia and New Zealand, clothing was rationed on point plans. In the United States, a single "red point" program, using red stamps, grouped meats, butter, margarine, edible fats and oils, cheese, condensed milk and canned fish. A "blue point" program, using blue stamps, included canned fruits and vegetables, fruit juices, soups, baby foods, and for a limited time dried fruits, peas and beans, and preserves.

Certificate rationing involved issuance of a ration certificate or purchase permit only to those who could prove their need for the rationed goods. Some of the commodities rationed on this plan were household furniture in Germany and in the United Kingdom, automobiles and

tires in the United Kingdom and the United States.

Ration Currency.—Ration coupons were usually issued in series, differentiated by design, colour, numerals or letters. Designated coupons were usually valid for stated periods. In this way the number of coupons currently valid, which in effect determined ration demand, could be adjusted to available supplies.

For some commodities, retailers were required to detach ration coupons. For others they cancelled coupons presented to them in exchange for rationed goods. When cancellation was required, the consumer was permitted to buy only from the retailer with whom he was registered. The retailer used his registration for obtaining replacement stocks. When coupons were detached, they were used as money is used for buying goods.

Ration "currency" passed through trade channels to the producer, the manufacturer or the primary supplier who in turn accounted for it to rationing authorities by showing a balance between goods sold and currency received. Great Britain and the United States used their nations' banks to handle ration currency. The United States also used one-point "tokens" to facilitate retail transactions and to reduce the volume of paper stamps handled.

Food.—For most of the world, rationing during World War II meant food rationing. It was the sole rationed commodity for which all consumers were eligible for individual weekly or monthly shares.

The severity of the civilian food ration varied widely with productive resources of the country, the proportion of the supply needed for the armed forces (or for Allied or occupying armies), with availability of transportation, the extent of dependence on imports and ability of the central government to control supply from the point of production to ultimate consumption.

With effective central and local administration and a level of supply reasonably adequate to meet minimum consumer requirements, rationing proved to be the most satisfactory way of maintaining fair distribution. But when supplies of civilian goods fell below minimum requirements, both price control and rationing were extremely difficult to administer. They failed altogether in Greece, and for a time in France, during the German occupation, in areas of the middle east and in much of China and India. Mass feeding and local distribution of foods available from time to time provided substitute measures.

In countries which normally produced most of their food, including the United States, Australia, New Zealand and Canada, rationing first became necessary for imported foods such as coffee and sugar. Tea was rationed in Australia and in New Zealand. As requirements of the Allied forces increased, and consumer purchasing power expanded, it became necessary to broaden food rationing in these countries.

In areas dependent on imports for a substantial part of their food supplies, it was difficult to make necessary quantities available. Germany met this problem during most of the war by drawing heavily on occupied areas to make up its own deficits, leaving critical distribution problems in such areas.

In the United States, sugar rationing began in the spring of 1942. A year later items already listed under the "blue" and "red" point programs were added. Coffee was rationed for nine months beginning Nov. 29, 1942.

Canadian rationing was less extensive than that of the United States. Sugar, butter, meat, preserves, coffee and tea were all included at one time though the list of rationed foods changed as supplies fluctuated.

In Germany and German-occupied Europe, food rationing was considered "total," since virtually no foods were available outside the ration after potatoes were rationed in 1942. Even restaurant meals required ration coupons.

In the soviet union, all staple foods were included in the ration system, but not the entire food supply. In addition to the ration, consumers with money could buy extra food in a legal price-free market in which collective farmers could sell their "share in kind," or in a price-controlled government store in which prices were comparable to those in the open market but much higher than prices of the rationed supply.

Contrasted with "total" food rationing in most of German-controlled Europe, such important basic foods as bread, flour, potatoes, fresh vegetables and home grown fruits remained ration-free in the United Kingdom.

Governments of the middle and far east, except Japan, were concerned primarily with control of prices and supplies of bread and bread grains, their principal foods. Adoption of uniform rationing was seldom practicable for broad areas, and formal rationing was used primarily for distribution of food to urban populations.

In Japan, food rationing began in 1941 and became progressively more severe as the war continued. As shortages increased, the government found it necessary to control all staple foods, setting aside quantities to meet military requirements and distributing the civilian supply through food corporations administered by the local governments.

In most South American countries, shortages of consumer goods, coupled with inadequate price control and swollen purchasing power, created maldistribution. But comprehensive rationing was not undertaken. The few ration programs that were introduced, were widely evaded.¹

Rations in Germany, Denmark and Bulgaria during the first four war years were equivalent in caloric value to prewar consumption though they fell sharply during the fourth year of war and after. By contrast with adequate German rations in the first years of war, rations of the non-German population in Poland equalled only 50% of prewar consumption, while Jews were limited to half the ration of the Poles—a level so low that it meant starvation for those unable to add to it in some way.

Other countries fell between these extremes. Rations in northern Italy and in France were from 50% to 70% of requirements based on prewar consumption; in Belgium, Norway, the Baltic states and Slovakia they were 70% to 90% of requirements. The Netherlands, Finland and the protectorate of Bohemia-Moravia appeared to suffer little serious caloric deficiency.² Consumption in occupied Russia was severely curtailed, though steady improvement was achieved after the occupying forces were pushed back to Germany.

When nearly all foods were rationed, it was necessary to provide extra or "differential" rations for those who needed more or different foods than the general ration provided. Extra food for workers in heavy industry, special diets for the sick, milk for children and nursing mothers—these and other food needs that could not be met by increased consumption of unrationed foods, were met in most countries by differential food rationing.

In the soviet union, in Germany and in most of occupied Europe, several categories of consumers were established according to their food requirements. The four main categories of consumers in Russia included: manual workers, office workers, adult dependents and children under 13. Manual workers received the highest rations;

children received extra rations of milk and dairy products. In the United States, meat and fats and oils became very scarce in the spring of 1945, and demands of miners led to establishing direct differentials for them and for loggers.

While it was not necessary to differentiate as sharply between categories of consumers in the United Kingdom as in countries with total food rationing, differentials were provided in three ways. (1) Different types of ration books, representing different food allowances were issued to adults, to children from 5 to 13 years, and to children under 5 years. The child's ration of meat was one-half that of adults, and children under 13 were not permitted a tea ration. Children under 5 had preference in buying milk, eggs, oranges, cod liver oil and vitamin preparations, also available to expectant and nursing mothers; (2) a canteen feeding program for workers in industry provided substantial ration-free additions to the diet; (3) feeding programs were established in schools.

Restaurant meals were unrationed, though restrictions were placed on the allowances of foods served.

Clothing and Textiles.—In the United Kingdom, and virtually everywhere on the continent of Europe, clothing rationing was as severe as food rationing. Under the point system employed, consumers used their points for articles of their choice from the limited supplies available. Differential rationing was necessary to provide some workers with articles such as industrial footwear or heavy outer garments.

Clothing rationing began in Germany in Nov. 1939 and in the United Kingdom in June 1941. The level of rationing in both countries was sharply below prewar use and inadequate to meet normal wardrobe replacement. Clothing was also rationed in New Zealand and Australia beginning in 1942.

The United States considered rationing in the spring of 1942, but optimism about the course of the war and resistance to additional economic controls caused the plan to be discarded. In consequence, clothing and textiles became increasingly scarce in the last two years of the war. Severest shortages developed when demobilized men began to put a heavy demand on already depleted stocks of suits, overcoats, shirts, while production lagged.

Standardization of apparel and production of utility textiles greatly aided clothing rationing in Britain, Germany, Russia and in occupied Europe. When very short supplies of such items as shoes and heavy outer garments made it necessary to superimpose the purchase permit plan on the point rationing program, consumers were able to obtain these articles only if they could meet a strict test of need.

Furniture.—Furniture and household equipment were strictly rationed in Great Britain and on most of the continent of Europe. The list of eligibles was restricted to new families, to those who had lost furniture through bombing raids and similar cases. Heating and cooking stoves and mechanical refrigerators were the only household goods rationed in the United States.

Fuel and Fuel Oil.—Fuel was rationed on most of the continent of Europe, where a variety of plans drastically curtailed consumption. In Great Britain, a fuel rationing program was completed in the spring of 1942, but resistance to further rationing and belief that voluntary restriction would be more satisfactory, led to postponing formal rationing several times. Instead, a series of restrictive orders was issued. Voluntary restriction, based on percentage of use before the war, resulted in many inequities which brought protests.

¹Canada Wartime Prices and Trade Board, *World Inflation*, (July 1944).

²League of Nations, *Food Rationing and Supply*, p. 40, (1944).

English housewives waiting in line for fresh eggs imported from Canada. This and other food items became increasingly scarce as World War II progressed, and extensive food rationing was still in force on Dec. 31, 1946

Fuel oil was rationed in those parts of the United States heavily dependent on it for heating and cooking. Consumers were required to register with a single dealer.

In the United States, with its high per capita rate of automobile owners, gasoline rationing was important and controversial. All automobile owners were provided with a basic ration, the amount fluctuating with the level of supply. Additional rations were provided for "home to work" driving, and preferential rations were given those with occupations considered essential to the war effort or to community health and welfare.

Gasoline use was restricted to a few essential users in most other areas of the world, the amount dependent on imports.

Motor vehicles, tires and equipment were rationed in most countries where they were available.

Other Items.—Many less important items were either rationed or restricted in use, as tobacco in Germany and in other parts of Europe, wine in France, alcoholic spirits in parts of Europe and in parts of the United States. Limits were also imposed on rail travel in most countries in Europe. Air travel was subject to priorities in most of the world.

Soap shortages developed in every country as the result of worldwide shortages of fats and oils. Rationing helped distribution somewhat in the United Kingdom and on the continent of Europe, but soap was almost unavailable in some areas for long periods. In the United States, where the supply and rationing agencies recognized the need for rationing, administrative difficulties and trade resistance kept the program that was planned from being put into operation.

Continued price control and rationing were necessary even after the close of the war, pending return to normal production and restoration of transportation facilities, to get adequate distribution of still limited supplies.

Some Allied countries instituted a tighter postwar rationing program than would otherwise have been necessary in order that part of their food supply might be used to re-

lieve famine or near-famine conditions in the Balkans, Italy, Poland, some parts of western Europe, India and China.

In the spring of 1946, for example, with most grain reserves in the world depleted, the United Kingdom rationed bread for the first time.

The concept that the general welfare was served by assuring minimum living standards to the population as a whole was greatly broadened by wartime experience. In the United Kingdom, the British dominions and the United States, general improvement in standards of living and maintenance of adequate levels of living for all, permitted the maximum national effort to be exerted in prosecution of the war.

In most of the western world, this concept of maintaining minimum living standards for all, in peace as well as in war, was growing.

The one long-term effect of wartime rationing might be to increase the determination of all nations to assure their peoples freedom from want. (See LAW; PRICE ADMINISTRATION, OFFICE OF.)

Rayburn, Sam

Rayburn (1882—), U.S. legislator and politician, was born Jan. 6, 1882, near Kingston, Tenn. A graduate of East Texas college, he studied law at the University of Texas and began practice in Bonham, Tex. Elected to the U.S. house of representatives in 1912, he assumed his seat March 4, 1913; thereafter he served in this post from the 63rd through the 80th congresses. Rayburn, who was majority leader for the 75th and 76th congresses, was elected by acclamation, Sept. 16, 1940, to succeed William B. Bankhead as speaker of the house in the 77th congress. While Rayburn supported Pres. Roosevelt on foreign policy, he was antipathetic to many of the New Deal's domestic measures. He was renominated for speaker of the 78th and 79th congresses. Although re-elected to the 80th congress, Nov. 5, 1946, the Republicans, having won a majority, elected Joseph W. Martin, Jr., to succeed him as speaker, on Jan. 3, 1947.

Rayon and Other Synthetic Fibres

The world produced an average of 2,200,000,000 lb. of rayon annually during 1937-46; in the previous decade, the average per year was 650,000,000. In that contrast was illustrated the phenomenal rise of the world's youngest textile fibre. The ten years after 1937 saw the continued rise of the filament rayon first introduced on a commercial scale following World War I, and the marked growth of rayon staple. In 1936 the production of rayon staple was 299,000,000 lb. The peak of world production during the decade was in 1941, when 1,563,000,000 lb. went into cloth that displaced cotton, linen and wool, all of which it could be made to resemble. In that year, Germany alone turned out 640,000,000 lb., with Japan and Italy following in second and third place (296,000,000 lb. and 292,000,000 lb. respectively). The United States ran fourth with 122,000,000 lb. Totals of world production of both filament and staple types are shown in Table I for the ten-year period.

Table I.—World Rayon Production, 1937-46
(Millions of Pounds)

	Filament Yarn	Staple	Total Rayon
1937.	1,204	622	1,826
1938.	996	911	1,907
1939.	1,150	1,147	2,297
1940.	1,182	1,293	2,475
1941.	1,272	1,563	2,835
1942.	1,200	1,480	2,680
1943.	1,163	1,410	2,573
1944.	1,033	1,049	2,082
1945.	934	596	1,530
1946.	1,100	700	1,800

The upward trend in production was interrupted in 1942 by war losses in several of the important countries, notably Italy, Japan, France, the Netherlands and Belgium. In Italy, total production dropped from 318,000,000 lb. in 1942 to 6,000,000 in 1945. Germany, too, in spite of the fact that it depended almost entirely on rayon in place of lost cotton and wool supplies, decreased production from the high of 902,000,000 in 1943 to 250,000,000 in 1945. Great Britain and the United States, on the contrary, showed an increase during the period. In 1942 British production was 124,000,000, and that of the United

States 632,000,000. In 1945 the British total was 145,000,000 and in the United States, 792,000,000 lb. In 1946 the United States topped its previous records by producing 853,900,000 lb. of rayon filament yarn and rayon staple, thus accounting for about 47% of the world total.

Rayon's Coming of Age.—In 1937 many of the uses for rayon that later became commonplace were discussed only as new ideas. Rayon tires for automobiles, rayon sails for boats, rayon sheer hosiery were reported as innovations, and there was constant discussion as to the continued growth of rayon dress fabrics. In Sept. 1937, the Federal Trade commission opened hearings in Washington, D.C., on the proper identification of rayon or manufactured cellulose fibre in yarn and manufactured articles. The commission ruled on Oct. 26 of that year that it was an "unfair trade practice" to sell rayon fibre or articles made therefrom without disclosure of the fact that it was rayon. Rayon was officially defined as a generic term for manufactured textile fibre or yarn produced chemically from cellulose or with a cellulose base regardless of whether it was made under the viscose, acetate, cuprammonium, nitrocellulose or other processes. The rules were announced by the United States governmental agency as a protection of the purchasing and consuming public and included references to the qualifying use of the word rayon when fabrics were described as taffeta, chiffon, crepe, etc.—terms commonly used in reference to silk fabrics. But the rules actually resulted in the high lighting of rayon as the fibre of which almost all dress fabrics and many upholstery fabrics were being made in all price ranges. The day following promulgation of the rules, retail stores throughout the United States, because of the requirements, used the word rayon freely in their advertising of fabrics, household furnishings and garments. The extent to which the fibre had

U.S. mountain troops climbing with the aid of nylon ropes. Nylon proved a suitable rope material because of its strength, resistance to abrasion on rocky terrain, and elasticity

748 taken hold of the textile market was revealed for the first time. From then on, rayon was an accepted member of the textile family, and appreciation of its progress as a fibre adaptable to many uses became publicly recognized. The new rules meant revision of many statistical compilations which had not previously separated rayon from silk data. Government reports were revised, and text books were rewritten.

The invasion of rayon into the silk field was already an accomplished fact by the end of 1937, but its competition with cotton fibre was not recognized until April 1938, when it was proposed in the United States Senate that a tax be imposed on rayon yarn at a flat rate of six cents per pound to help pay the subsidy to cotton farmers. The bill itself was introduced by a senator from a wool-growing state, who may have cast a prophetic eye to the time when rayon staple would invade the wool market, as actually happened on a wide scale during World War II. The tax was not levied, but the reason for its proposal continued to be a matter of contention throughout the period.

In Oct. 1944, the Southern Regional Research laboratory at New Orleans, La., published a *Survey of Development and Use of Rayon and Other Synthetic Fibers* which carried in its introduction the following: "Farmers in the United States have several good reasons for carefully studying the production of synthetic fibres in this country and abroad. Rayon, the most important of these synthetic fibres, has already displaced considerable quantities of both cotton and wool, as well as silk, for use in clothing and household fabrics. It is now also proving to be an important competitor in certain industrial uses. For example, in the field of tire fabrics, the largest single use for cotton in the United States, rayon is now being used extensively for certain classes of military vehicle and airplane tires as well as for large size commercial truck and bus tires. . . ."

In Aug. 1938 the U.S. Rubber company and the Good-year Tire and Rubber company announced the marketing of rayon passenger car tires for the first time. In 1938 also came the first trade announcement of nylon as a new, non-cellulose base yarn which could not be accurately described as rayon but was recognized as an important step forward in synthetic fibres.

So rapidly were new man-made fibres developing at this time that in Feb. 1939, the *Journal of the Society of Dyers and Colourists* in Great Britain issued a classification of such fibres as follows:

- Group I—Rayon regenerated cellulose fibres made up of the viscose, cuprammonium and nitro-cellulose rayon yarns and staple fibres
- Group II—Rayon—Cellulose derivative fibres made up of cellulose acetate yarns and staple fibres
- Group III—Natural protein fibres, primarily made from milk casein and produced in the form of short staple fibres rather than continuous filament
- Group IV—Nylon—synthetic protein-like fibre made from coal, water and air and officially defined as "Nylon is the generic name for all materials defined scientifically as synthetic

fibre-forming polymeric amides having a protein-like chemical structure derivable from coal, air and water or other substances and characterized by extreme toughness and strength and the peculiar ability to be formed into fibres and into various shapes such as bristles, sheets, etc."

Group V—Synthetic resin fibres with an all chemical base such as vinyl or acrylic and which do not utilize as raw materials any vegetable or animal substances, illustrated by Vinyon in the United States.

This 1939 summary mentioned most of the synthetic fibres used in 1946, at least those in the general commercial market, with the exception of spun glass fibre, which is not synthetic in its nature and is not rayon (cellulose base). Aralac, used during World War II for its woolly appearance, is a natural protein fibre of milk casein.

Rayon's World Leadership.—The leadership in rayon production held by Germany from 1937 to 1944 was taken over by the United States, when Germany's total production of 650,000,000 lb. was exceeded by the 723,900,000 lb. from United States plants. Germany's world record of 902,000,000, in 1943, had yet to be equalled, although the United States was rapidly approaching it with 854,000,000 in 1946. Whether Germany would regain its position was not apparent by the end of 1946. During that year, rayon producing in some of the war damaged countries recovered surprisingly. Belgium, Czechoslovakia, France, Great Britain, Italy and the Netherlands showed outstanding gains. Germany and Austria and Japan remained at low levels. But from past experience, most industry men agreed that Germany and Japan presented the most formidable potential competition.

With the beginning of World War II in Sept. 1939, U.S. rayon yarn found its way into the export market to replace the former shipments to South and Central America from Italy, Germany and Japan. Italy continued to maintain its position, especially in Mexico, for the first years of the war, but Germany and Japan were cut off. In the summer of 1940 exports of U.S. yarn, hitherto not called for because of higher prices, were noticeably increasing, especially in rayon staple and waste. In 1937 United States exports of rayon were limited to filament yarn and amounted to 1,281,991 lb. By 1946 the exported yarn totalled more than 19,000,000 lb., of which about 14,900,000 was filament yarn and 4,100,000 staple and waste. Even so, the return to prewar conditions was indicated in the fact that the

Huge turnout in response to a department store's announcement offering nylon hosiery for sale in Jan. 1946. By the close of the year, this article was removed from the list of scarce consumers' goods for the first time since the beginning of World War II

1946 exports were lower than 1944 and 1945. The peak year, 1945, saw 26,600,000 lb. of rayon going out of the United States; 22,000,000 of filament yarn and 4,600,000 of staple and waste.

Users of Rayon Yarn.—Distribution of filament rayon yarn in the United States offered a basis of study as to the users of rayon yarn and the development of those uses over the period of 1937–46. In 1937 hosiery manufacturers used 4.6% of the total shipments. Woven fabrics took 77.7%. Tire manufacturers, then only starting their interest in rayon, used only .3%. By 1946 hosiery manufacturers, in spite of consuming twice as much poundage, used only 33% of the total. The woven fabrics used 51.4%, but the tire manufacturers received 31.5%.

The ten-year record of filament rayon yarn shipments by trades (Table II) revealed the sharp jump in use of rayon for fashioned hosiery, brought about by the loss of silk in the summer of 1941. It also disclosed the growth of rayon warp knitted fabrics, beginning in 1940 and continuing through 1946. The rayon tire increased its demands 237% between 1937 and 1946.

Table II also shows the effect of releasing nylon for civilian purposes during 1945 and 1946. Rayon for fashioned hosiery dropped from the high of 33,100,000 lb. in 1943 to 6,100,000 lb. in 1946. This confirmed the objections raised in the summer of 1941 by rayon yarn producers and rayon fabric weavers to the demands by government war agencies that a substantial amount of yarn be taken from the weavers and giv-

en to the hosiery manufacturers. Both groups contended that hosiery makers were not serious users of rayon and would revert to nylon as soon as possible. It was also contended that manufacture of fabrics for clothing was a more essential use than hosiery. In the years of 1942–45, when hosiery demand was high, a decreasing amount was allotted to fabric weavers, despite marked increase in consumer demand for rayon garments of all kinds.

Rayon fabric manufacturers not only had to supply increased amounts of fabric to their regular customers, but to a large group formerly using cotton fabrics, no longer available because of military demands, and to buyers in foreign countries who had never before shown interest in the generally higher cost, higher-priced U.S. rayon textiles. Rayon filament yarn was used for the most essential fabrics, such as linings for men's and boys' clothing. Dress fabrics were made of spun rayon, in which the rayon staple is combed into a yarn in a manner similar to the manufacture of raw cotton into cotton yarn. Rayon fabrics began to assume a place of their own in official statistical records. The use of rayon in fabrics had been so experimental that official census figures published by the U.S. department of commerce prior to 1939 were not considered too exact. Cotton and silk weavers were both using rayon extensively, and in making their reports to the government, there was some confusion as to whether the fabrics should be classed as being of one fibre or another.

In May 1940 the Textile Economics Bureau Inc., a statistical reporting agency for the rayon industry, published a rayon fabric classification, the first of its kind: 119 fabrics were listed in five groups; filament rayon, filament rayon mixtures, all spun rayon, spun rayon blends with other fibres and spun rayon mixtures. In Aug. 1941 when wartime price controls were first suggested in the United States to protect essential civilian supplies, the basis of the price regulation was a similar classification. Later it was expanded to about 250 fabrics, representing the staple types of rayon fabrics which by 1942 were established on the market.

The War Production board and the Office of Price Administration early authorized the collection of production and shipment statistics in detail from the producers of rayon fabrics to meet the demand for information about the newly developed industry that had not been hitherto available. These reports, first published in 1943, gave production of fabrics by types, consumption of rayon by the mills and later machinery operation in three month periods. A summary of the reports for 1943–46 is shown in Table III, combined with census reports for 1937 and 1939. In addition to the rayon fabrics, the complete reports included nylon, silk and other fabrics, as made in the mills customarily working on rayon. Among them were wool and rayon mixtures, containing less than 51% of rayon. These mixtures were used to eke out the supply of raw

Chemical extracts of casein solution, from skimmed milk—source of aralac, a versatile synthetic fibre. This picture shows aralac being reeled out of the acid bath which changed it from a liquid to a fibre

wool at the beginning of World War II, when military needs were expected to be heavy; but despite later comparative plenty in wool fibre, the new fabrics continued in demand for men's and sports wear. The reports also reflected a shortage of a standard type of rayon, 150 denier pigment yarn, that comprised the bulk of the popular priced dress materials prior to the war. Their disappearance from the market caused a good part of the complaints as to shortages of desirable materials. The production of 150 denier yarn was cut sharply due to the conversion of spinnerets for the coarser yarns to tire yarns, badly needed by the military.

Rayon and Synthetics in the War.—Rayon was the first textile material subject to U.S. civilian allocation during World War II. When commercial relations with Japan were terminated in July 1941, the U.S. government immediately took steps to purchase all available raw silk for whatever military requirements might arise. At that time, silk was the only material used in parachute fabric. Manufacturers of hosiery and fabrics who were still using silk immediately pleaded for help in securing yarn to continue their supplies of civilian necessities. Rayon yarn had been difficult to obtain for some time. Early in July, it was stated that it had become necessary to allot yarn to customers because of the limited supply. On Aug. 2, 1941, the Office of Price Administration (OPA), division of civilian supply, ordered rayon producers to set aside 10% of their daily output and 10% of their stocks for a government pool. The rayon had to be suitable for hosiery and other products formerly made of silk. Hosiery makers were allotted 70% of the pool and other manufacturers the remaining 30%. On Aug. 23, the OPA issued mandatory ceiling prices for 52 constructions of rayon gray goods.

The prices were stated to average 10% less than market quotations, and the ceiling price regulation of rayon gray (unfinished) goods remained in effect until Dec. 1946, with no revisions after April 1942. Some South American countries, the U.S.S.R., South Africa and Australia received export quotas of the rayon yarn by government decree. What was first considered strictly a civilian industry destined to supply civilians with fabrics developed into a war industry of substantial importance and size.

The use of rayon fabrics and materials in military equipment was extremely diversified. Parachutes of all kinds were made of rayon and nylon as well, although the latter was restricted to the escape chute used by air force personnel. Cargo or aerial delivery chutes employed extensively in the Pacific area to reach out-of-the-way posts in jungles and on isolated islands, carried food, supplies and mail. Flare chutes were used for signalling. Luminous satin strips were laid on airfields to guide planes where landing lights were impractical. Marksmanship was practised by aid of tow targets, huge cone-shaped parachutes sometimes made of rayon interlaced with copper wire to keep them rigid in the air. Low-level bombing was made possible by use of the fragmentation bomb parachutes. The bomb was dropped from as low as 25 foot altitudes by the plane; the parachute delayed its action sufficiently to permit escape of the fliers. Many hundreds of thousands of these parachutes were made, and more than 22,000,000 yd. of fabrics were woven for them.

In addition to rayon, synthetics such as nylon and glass fibre were extensively used. Nylon, particularly, was found

of great value in equipment of parachute troops and jungle fighters. Ski troopers were given tents of nylon cloth because of its light weight and strength, and because it could be weather-proofed successfully. Experienced aviators soon preferred nylon to silk personal parachutes. The fibre did not mildew as silk did; it kept cleaner because of its less absorbent properties, and its creases fell out more readily on being repacked. Nylon mosquito bars were impervious to jungle "rot," were more airy, lighter in weight and resistant to moisture and dirt. Sleeping hammocks were also made of nylon cloth for the same reasons, and by the close of World War II, plans were under way to utilize the fibre in many articles of clothing where light weight, ease of cleaning and strength were required.

Glass fibre fabric was fused into body armour for anti-flak suits. It was also used in many instruments for the military. The quartermaster corps of the army became so interested in the possibilities of the synthetic fibres that it retained for peacetime study a corps of technical men working for the duration of the war. A report on the accomplishment of the work was made in 1945 to the textile industry as an example of what technical research could do in manufacturing materials to meet a need rather than a weave.

Nylon was also shipped to Great Britain during World War II. Results of experimentation in weaving the fibre were sent to British weavers for their guidance, and yarn and polymer for making yarn were supplied to the British industry. The British-owned rayon producing organization (largest in the United States)—Viscose corporation—was sold on the U.S. market on March 16, 1941. This was considered a bitter blow to British rayon leadership but the sale was said to be in line with the policy of the British government to sell its investments in the United States for dollar exchange. The corporation was taken over, however, primarily by U.S. associates of the original firm.

The total rayon fabrics supplied for war uses during World War II was approximated at 912,000,000 lin.yd. (See also CHEMISTRY; CHEMURGY.)

Reconstruction Finance Corporation

The Reconstruction Finance corporation, created by congress on Jan. 22, 1932, began operations as a lending

agency on Feb. 2, 1932. On June 30, 1946, authorizations for loans and other purposes totalled \$40,557,000,000. In addition, the corporation had outstanding authorizations aggregating \$674,000,000, which were made under conditional agreements.

Capital stock of the corporation was originally fixed at \$500,000,000, all of which was subscribed by the secretary of the treasury on behalf of the government of the United States. Pursuant to the act, approved June 25, 1940, the corporation retired \$175,000,000 of its capital stock at par. The corporation's succession, originally established at ten years, was extended five years to Jan. 22, 1947, and, subsequently, as an interim measure, was again extended by the 79th Congress to June 30, 1947.

Recovery Period, 1936-40.—Starting with 1936 and ending with 1940, when the national defense and war production period began, the United States was undergoing convalescence from the worst depression in its history. During this period the need was recognized of giving special assistance to owners of real estate and holders of real estate mortgages. RFC, while not dealing directly with individual borrowers under federally-insured mortgages, nevertheless assisted them through the creation of a market for such mortgages. Its activities along this line were directed toward creating confidence in real estate and thereby encouraging home building. In addition, a series of floods, hurricanes and other disasters of such magnitude that individual communities could not, themselves, meet the needs of distressed persons in the community, led to the creation of a special organization designed solely for the purpose of aiding disaster victims.

The RFC Mortgage company was formed at a time when practically no mortgage money was available to deserving borrowers to protect their business properties from foreclosure, and to aid in the reorganization of properties covered by excessive mortgages and mortgage bond issues. Congress authorized the corporation in Jan. 1935, to invest in the capital stock of mortgage companies up to \$100,000,000 when any such investment was approved by the president, following which the corporation, with the approval of the president, subscribed for the capital stock of the RFC Mortgage company March 14, 1935, in the amount of \$10,000,000, later increased to \$25,000,000. The stock was all owned by the RFC.

The Federal National Mortgage association was organized by RFC on Feb. 10, 1938, under authority of the National Housing act, which provided for organization of national mortgage associations. Owned and operated by RFC, it was established to deal exclusively with mortgages insured by the Federal Housing administration. It had \$10,000,000 capital, paid-in surplus of \$1,000,000 and, at June 30, 1946, had surplus and reserves aggregating \$2,598,000. It had paid dividends to RFC aggregating \$20,500,000.

Disaster Loan corporation was established following the Ohio river flood in Jan. 1937, when congress, in response to a nationwide desire to assist flood victims, instructed RFC to organize such a corporation with capital up to \$20,000,000 to be used in making loans to those who suffered losses from flood or other catastrophes during 1937. The Act was later amended to include such losses that occurred in the years 1936 and 1938. Offices for making disaster loans were established in cities throughout the Ohio river valley immediately after the corporation was organized, and 7,555 loans, aggregating \$8,805,051, were authorized as a result of the Ohio river flood, of which \$6,785,729 was disbursed. Offices were opened the following year in

numerous New England cities for the purpose of making disaster loans as a result of the hurricane that occurred in Sept. 1938. Effective July 1, 1945, this corporation was dissolved, and its functions, powers, duties and authorities were transferred to the RFC.

War Activities of RFC, 1940-45.—The axis nations, which early in the 1930s had converted their economies to a wartime production basis, had the advantage of a head-start on the nations with which they were later at war. Sensing the gravity of the peril, the United States launched a program in the summer of 1940 designed to strengthen America's military might. As part of this endeavour, congress empowered the Reconstruction Finance corporation to lend its full credit facilities to producers of war goods. An important part of this program had a direct bearing on small business. It became apparent early in the defense and war periods that every available plant capable of engaging in war production should be encouraged to expand its facilities and, where necessary, to re-tool its plant in order that all manufacturers could contribute efficiently to the war effort. This operation affected not only the large suppliers of products needed by the military, as well as the civilian, front of the country, but also tens of thousands of sub-contractors, sub-sub-contractors and other small suppliers. In addition, the Reconstruction Finance corporation was authorized to create new production facilities, to install special-type machinery in privately-owned plants, and to create stockpiles of critical and strategic materials for use in war production.

To enable RFC to perform these functions, the president, on June 25, 1940, signed an act of congress authorizing the corporation to act through subsidiary corporations to be created by it, for purposes of national defense; to build and operate plants and facilities for the manufacture of matériel; to procure supplies and equipment, and to buy materials declared by the president to be strategic and critical. The subsidiaries created under this authority were the Defense Plant corporation, Rubber Reserve company, Metals Reserve company, Defense Supplies corporation, War Damage corporation, U.S. Commercial company and Petroleum Reserves corporation.

Another subsidiary, the Rubber Development corporation, was established under the laws of the state of Delaware.

Defense Plant corporation, Defense Supplies corporation, Metals Reserve Company and Rubber Reserve company were dissolved, effective July 1, 1945, and their functions, powers, duties and authority were transferred to RFC.

Defense Plant corporation was created by the RFC on Aug. 22, 1940, primarily to build and operate plants and facilities for the production of war matériel and to perform other acts essential to the U.S. national defense. The corporation made authorizations totalling \$8,972,000,000 for 2,486 projects. An additional \$2,157,000,000 was authorized for machine tools pool, for the gauge and cutting tool program and for surplus machinery warehouses. Of the aggregate amount of authorizations, \$8,468,000,000 was for the construction and operation of 2,260 facilities for the production of a wide range of products, including steel, magnesium, aluminum, alumina, chemicals, metal fabricating, aviation gasoline, gas storage, synthetic rubber, a tin smelter and floating power plants. Authorizations for 226 nonmanufacturing projects totalled \$504,000,000 and included flying schools, housing, six pipe lines, among them the Big and Little Big-Inch pipe lines.

Both in number of projects and the amount authorized, production of aircraft and parts was the major activity of the Defense Plant corporation, a total of \$3,208,000,000 being authorized for 620 facilities. In many of these, components and accessories were manufactured for assembly or use in repairs elsewhere while in others complete planes were made. DPC's second biggest task was making available facilities for producing the steel and pig iron required to fill wartime needs, the sum of \$1,148,000,000 being authorized for 225 facilities, including those used in the production of coke and ore. Third largest program was the authorization of \$1,056,000,000 for 159 synthetic rubber projects.

Other authorizations and the manufacturing projects for which they were made included: Aluminum, \$842,000,000 for 99 projects; aviation gasoline, \$324,000,000 for 45 projects; chemicals, \$214,000,000 for 199 projects; machine tools, \$91,000,000 for 166 projects; magnesium, \$449,000,000 for 53 projects; minerals, \$178,000,000 for 79 projects; ordnance, \$495,000,000 for 119 projects; radio communication and field equipment, \$120,000,000 for 167 projects; shipbuilding, including propelling machinery and parts, \$201,000,000 for 100 projects; other manufacturing facilities, \$142,000,000 for 229 projects.

Authorizations for 66 flying schools totalled \$46,000,000; for 29 housing projects, \$29,000,000; for 6 pipe lines, \$189,000,000; for 110 transportation projects other than pipe lines, \$234,000,000, and for 15 other nonmanufacturing facilities, \$6,000,000.

Rubber Reserve company was organized by RFC June 28, 1940, for the purpose of acquiring stockpiles of raw rubber and of developing and supervising the operation of facilities for the production of synthetic rubber. In Feb. 1943, at the request of the rubber director, RFC separated the development and procurement of natural rubber in the western hemisphere from Rubber Reserve company and carried on that operation through Rubber Development corporation, another subsidiary of RFC which was transferred on July 15, 1943, to the Office of Economic Warfare, and later transferred to the Foreign Economic administration, where it handled all natural rubber procurement in foreign countries.

Development of the synthetic rubber industry during the war emergency was a credit to the ingenuity and enterprise of U.S. business and was an outstanding example of the close co-operation of industry and government during the emergency. Some small plants for the production of synthetic rubber were first authorized early in 1941. The program was increased to an annual capacity in excess of 400,000 tons immediately after Pearl Harbor and, following the fall of Singapore, it was further increased. Rubber Reserve company's production of synthetic rubber was approximately 1,750,000 long tons, 737,000 tons of which were manufactured in 1944 and 800,000 tons in 1945. Synthetic rubber plants in the United States reached a capacity of at least 1,000,000 long tons of synthetic rubber a year.

Forty-seven chemical, petroleum, rubber and industrial companies were operating plants for Rubber Reserve company in 1946. In addition to the production of synthetic rubber, the plants manufactured 28,400,000 gal. of ethylbenzene and approximately 14,200,000 gal. of cumene used in the manufacture of aviation gasoline.

Including imports by the trade, crude rubber importations from 1940-46 were more than 2,280,000 long tons. Of this the Rubber Reserve company imported 1,051,000 tons of natural rubber, including 90,000 tons bought from the Commodity Credit corporation.

Before the war, natural rubber cost from 18 to 20 cents a pound. Some of the synthetic plants produced rubber at less than those figures. The cost of production, exclusive of plant amortization, was higher in 1944, being approximately 33 cents a pound, because more than 60% of the rubber had to be made from high-priced alcohol instead of petroleum.

Metals Reserve company was created June 28, 1940, to produce, acquire, carry and sell, or otherwise deal in, strategic and critical materials, primarily metals and minerals in connection with the war program, performing these functions until July 1, 1945, when, under Public Law 109, 79th congress, it was consolidated in Reconstruction Finance corporation as the Office of Metals Reserve. The Reconstruction Finance corporation, as of Dec. 31, 1945, had made total commitments for the procurement of strategic and critical minerals and metals aggregating \$6,024,000,000. Of this amount, \$2,762,000,000 had been disbursed and \$2,524,000,000 cancelled or assigned to industry or the Foreign Economic administration. Sales of these materials, made principally to industries engaged in war production, amounted to \$1,793,000,000. Stockpiles on hand cost \$611,105,000 and, in addition, there were assets largely consisting of advances to contractors, other receivables, mining equipment and supplies in the sum of \$98,400,000.

Losses through sale of materials within Office of Price Administration ceiling prices were \$54,400,000, a great many of the materials having been bought at more than ceiling prices. Losses through subsidizing domestic production of copper, lead and zinc from marginal mines and other metal subsidies aggregated \$238,000,000.

Purchases covered 75 different critical materials, and came from 51 foreign countries, 43 states in the United States, Alaska and the Philippines. Purchases were begun in 1940, well before Pearl Harbor, and continued throughout the war. Activities were continued through 1946 to meet civilian deficiencies as estimated by the Civilian Production administration.

Reconstruction Finance corporation, through its Office of Metals Reserve, also operated a tin smelter at Texas City, Texas, and the Nicaro Nickel plant in Cuba, and administered the premium price plan for domestic copper, lead and zinc.

Defense Supplies corporation, created Aug. 29, 1940, to purchase and stockpile strategic and critical materials other than rubber, minerals and metals, and to do other things necessary to the production and procurement of essential materials such as payment of extraordinary transportation costs on oil, coal, and sugar, loans and advances to contractors, was dissolved effective July 1, 1945, under Public Law 109, 79th congress, and was consolidated with the Reconstruction Finance corporation as the Office of Defense Supplies.

As of Dec. 31, 1945, the Reconstruction Finance corporation, through Defense Supplies corporation, had authorized total expenditures in the war effort aggregating \$12,324,000,000, of which \$1,446,000,000 had been cancelled or assumed by private industry. Disbursements for the purchase of strategic and critical materials, extraordinary transportation costs in oil, coal and sugar, loans and advances to contractors in connection with the purchase of materials, the payment of subsidies and other activities made necessary by the war were \$8,156,000,000. Receipts from the sale of materials, repayments of loans and advances and from other sources totalled \$6,122,000,000.

Principal subsidies were those paid on meat, butter, flour, crude oil from stripper wells, aluminum rod and bar,

woodpulp and extraordinary transportation costs. Subsidy payments through Dec. 31, 1945, on meat were approximately \$1,169,000,000; on butter, \$183,000,000; and on flour, \$244,000,000. Subsidy payments on the production of crude oil from stripper wells began Aug. 1, 1944, and total payments through Dec. 31, 1945, were approximately \$68,000,000. As of that date, all claims had not been paid.

Payment of extraordinary transportation costs included the movement of petroleum and petroleum products from the midwestern and the southwestern sections of the United States to the eastern seaboard at a net cost of \$337,700,000; the movement of crude oil from Texas and Louisiana to midwestern refineries at a net cost of \$14,700,000; the transportation of coal by rail to the New York and New England area at an approximate cost of \$49,900,000; and the transportation of sugar from the western section of the United States to the eastern seaboard at an approximate cost of \$24,900,000.

Loans and advances were made principally in connection with the construction of facilities for the production of 100-octane aviation gasoline. The corporation disbursed on loans and advances for this purpose \$130,200,000. Repayments aggregated \$87,000,000.

In addition, the corporation in Sept. 1941, agreed to purchase materials from the soviet union aggregating \$100,000,000, and advanced \$49,700,000 against the future delivery of such materials. As of Dec. 31, 1945, the soviet union had delivered materials on this contract to the value of \$46,000,000, as payment on the advances.

To enable the Army Exchange service to establish post exchanges speedily in all locations where troops were sent, the corporation authorized loans aggregating \$91,000,000, against which disbursements were made in the total amount of \$71,100,000. All of these advances were repaid from operations of the post exchanges.

Other activities of the corporation included the elimination of axis control of Latin-American airlines and bringing citizens of other American republics to the United States for training as aviation pilots and technicians.

An important activity was the operation of the various government-owned pipe lines for the transportation of petroleum and petroleum products. As of Dec. 31, 1945, the corporation had expended \$880,000,000 for the purchase of petroleum and petroleum products and in operating the lines. Receipts from the sale of the oils and operations of the lines totalled \$1,048,000,000. The pipe lines were operated for account of Defense Supplies corporation, and at very substantial profits.

War Damage corporation was organized by Reconstruction Finance corporation on Dec. 13, 1941, to provide governmental insurance against loss of or damage to property as a result of enemy attack. Organization of this subsidiary was necessary because of the uncertainties involved and the inadequacies of insurance reserves. War risk insurance on other than marine risks was practically unobtainable at the outbreak of the war. (See INSURANCE.)

U.S. Commercial company was created March 27, 1942, as a subsidiary of the Reconstruction Finance corporation. An executive order of July 15, 1943, transferred control of the U.S. Commercial company to the Office of Economic Warfare, which on Sept. 25, 1943, was consolidated into the Foreign Economic administration. On Sept. 27, 1945, certain functions handled by FEA through U.S. Commercial company were redistributed to RFC. The company served as the corporate agent of the Foreign Economic administration for the procurement and development of strategic

materials and essential foodstuffs, outside the United States, the operation of certain special projects for the army and navy in war zones, and the facilitating of American trade with areas with which direct commercial dealings were cut off or restricted because of the war.

The executive order which transferred U.S. Commercial company to the Foreign Economic administration provided that Reconstruction Finance corporation should furnish the funds necessary in its operations. RFC authorized loans to U.S. Commercial aggregating \$1,800,000,000, of which \$1,654,512,515 had been disbursed. Repayments totalled \$1,235,160,717. The U.S. Commercial company assisted in the restoration of the economies of occupied areas of Germany and Japan during 1946, and in facilitating trade with those areas as far as practicable.

Petroleum Reserves corporation was established by the Reconstruction Finance corporation on June 30, 1943, principally to buy or otherwise acquire reserves of crude petroleum. On July 15, 1943, it was transferred to the Office of Economic Warfare, and, on Sept. 25, 1943, was consolidated into the Foreign Economic administration. On Sept. 27, 1945, Petroleum Reserves corporation was returned to RFC. On Nov. 9, 1945, its name was changed to War Assets corporation which, until March 25, 1946, was responsible for disposal of surplus property. This corporation was dissolved on June 30, 1946.

In addition to the corporations mentioned above, RFC conducted some of its wartime activities through Rubber Development Corporation and Defense Homes corporation.

Rubber Development corporation, established under the laws of the state of Delaware, was organized to carry on all wartime activities connected with the exploration, development and procurement of crude rubber, balata, cryptostegia, guayule and other gums of similar utility in all areas outside the continental United States for which the United States assumed responsibility. It also engaged in the procurement of liquid latex, scrap rubber and reclaimed rubber and rubber products in foreign countries. On Sept. 25, 1943, the capital stock, including all of the issued and outstanding shares which were held by Reconstruction Finance corporation, was transferred to the control of the administrator of the Foreign Economic administration.

The order transferring Rubber Development to FEA provided that Reconstruction Finance corporation should furnish the funds necessary in its operation. RFC authorized loans to Rubber Development corporation aggregating \$275,000,000, of which \$254,613,554 was disbursed. Repayments from the sale of rubber to Rubber Reserve company have been \$172,497,782. Rubber Development corporation was returned to RFC by an executive order of Sept. 27, 1945.

Defense Homes corporation, established under the laws of Maryland, Oct. 23, 1940, though not a subsidiary of RFC, was managed by the latter until it was consolidated with the National Housing agency Feb. 24, 1942. The corporation was authorized to borrow from the Reconstruction Finance corporation not to exceed \$65,750,000, such borrowings to be repaid from the net income from operation of the properties during the preceding quarter after provision of adequate reserves for depreciation, vacancy losses, and the payment of all expenses and from proceeds of disposition.

The Post-War Period.—The promotion of a sound and enduring prosperity by extending adequate credit to

banking and business, with particular emphasis upon the needs of small business enterprises, became a major postwar objective of RFC. At the same time, the functions of Defense Plant corporation, Defense Supplies corporation, Metals Reserve company and Rubber Reserve company, defense subsidiaries merged into the parent organization July 1, 1945, were continued. Functions of the RFC Mortgage company and of the Federal National Mortgage association also were among major postwar activities of the agency.

RFC from the outset gave special attention to the needs of small business, approximately 90% of all its loans in number being for \$100,000 or less. In preparation for the problems of reconversion, the corporation initiated a nationwide study more than a year before V-J day. The survey revealed that adequate facilities to finance longer-term credit and capital needs of small enterprises were more essential than ever to the success of any prosperity program. This led to the development of the Blanket Participation agreement program, under which RFC agreed to guarantee not exceeding 75% of any business loan made to an eligible business borrower by a participating bank when requested by the bank to do so. Under this plan, RFC committed itself, subject to provisions of the agreement, to take over part of the loan, if the bank desired, upon ten days' notice. Nearly 5,000 banks had signed the agreement as of Sept. 12, 1946. In the event that banks were unable or unwilling to make business loans, RFC continued to accept applications for direct loans; however, applicants were enjoined first to apply to local banks for such assistance.

On June 5, 1946, a small business division was organized by RFC, the function of which was to deal with special small business problems; to develop and co-ordinate advisory services for loan applicants and borrowers; to cooperate with Veterans' administration and the department of commerce in matters pertaining to small business and to assist small business in buying surplus property. During the first six months of 1946, 6,408 business loans in the aggregate amount of \$294,264,549.17 were authorized, of which RFC's participation aggregated \$232,428,032.35. Banks' participations amounted to \$61,836,516.82. These amounts were exclusive of \$119,027,483.49, representing authorizations which RFC took over as a result of the transfer to that agency of certain functions of the Smaller War Plants corporation, as of Jan. 28, 1946.

Under the Surplus Property act, RFC was given authority, formerly exercised by Smaller War Plants corporation, to exercise its priority to buy surplus property for small business, enabling such enterprises to make their purchases after the needs of government agencies and veterans had been satisfied. During the four months ending July 31, 1946, 6,782 applications involving surplus property with an aggregate value of \$27,456,000 were consummated under the RFC priority, and an additional 10,722 applications had been received, many of which were in various stages of consummation.

The postwar functions of the former Defense Plant corporation were marked by orderly liquidation of plants and facilities, and involved contract termination, close-down, plant protection and maintenance, the designation of surplus plants and equipment as being available for disposal, and the continued operation of certain plants under lease agreement. Some 2,260 DPC projects were authorized during the war.

Some programs of the former Defense Supplies corporation were terminated on recommendation of sponsoring agencies, while others were continued. The sum of \$1,000,-

000,000 was included in the 1947 budget for payment of subsidies on flour and meat.

Principal functions of the former Metals Reserve company continued by RFC were the procurement of tin and tin ores and concentrates, copper, lead and antimony under directives from the Civilian Production administration and the Office of War Mobilization and Reconversion.

Because of the short supply, RFC continued to distribute to consumers all available synthetic and natural rubber, the corporation performing the functions previously handled by the Rubber Reserve company, which was dissolved July 1, 1945, and directing activities of the Rubber Development corporation, which was transferred back to RFC on Sept. 27, 1945.

The RFC Mortgage company maintained a market where financial institutions could sell Federal Housing administration insured mortgages to provide cash for making additional loans for other purposes. Since its organization the RFC Mortgage company had disbursed approximately \$353,000,000 for 66,174 mortgages and loans; had sold or collected 58,974 mortgages and loans, totalling \$313,762,000, and as of Dec. 31, 1945, had outstanding 7,200 loans totalling \$39,239,000.

Over \$117,000,000 of the amount disbursed related to war housing.

The RFC Mortgage company also established a market for veterans' home loans guaranteed or insured by the Veterans' administration, thus enabling private financial institutions to continue to make loans to veterans for the purchase or construction of homes.

Operations of the Federal National Mortgage association, created to assist in establishing a market for first mortgages insured under the National Housing act, as amended, were continued during 1946. As of March 31, 1946, the association had disbursed \$271,554,633 for 66,957 mortgages; had sold or collected on 64,552 mortgages totalling \$264,603,995, and as of March 31, 1946, had outstanding 2,405 loans totalling \$6,950,638.

Until March 25, 1946, when the War Assets administration took over, RFC was responsible for the disposal of many items of surplus property. From May 1, 1944, until the close of its program, surplus aircraft and capital and producers' goods costing \$12,912,000,000 was turned over to RFC for disposal. Aircraft costing \$6,904,000,000 accounted for considerably more than half of the total, and more than two-thirds of the planes, costing \$4,652,000,000, consisting principally of combat planes, were nonsalable. Industrial plants and real estate that cost \$3,496,000,000, and capital and producers' goods, such as chemicals, electronic equipment, machinery and miscellaneous items that cost \$2,512,000,000 accounted for the rest of the surplus inventory.

As of March 23, 1946, property that cost \$1,887,000,000, or 14.6% of the total turned over to RFC, had been sold or leased.

The sales record, involving property that cost \$1,328,000,000, showed a yield to the government of \$576,000,000, a return of 43.4 cents on the dollar. The return from industrial plant and real estate sales was 59.6% and from aircraft 16.6% of cost. (C. B. H.)

Reconversion, Postwar

See BUSINESS REVIEW; WAR PRODUCTION.

Red Cross

American Red Cross.—Supported entirely by voluntary contributions, the Red Cross conducted the most diversified program of its history during the decade ending in 1946. Within that period its primary obligation of assistance to the armed forces expanded to undreamed of proportions, it carried out the largest disaster operation in its history, furnished relief valued at \$178,474,068 to civilian victims of war in some 40 countries and at the same time maintained and expanded its long-standing programs of community service at home.

With the end of World War II, the American Red Cross (ARC) set itself to aiding rehabilitation and reconstruction, to strengthening community programs and to continuing the domestic and overseas program on behalf of the armed services.

In 1941 the organization had 9,866 chapters and branches, supported by 9,190,474 adult and 9,749,053 junior members. At home and overseas on Dec. 7 of that year were 1,087 Red Cross men and women professionally trained to assist men in uniform with the multiplicity of problems which the expansion of the U.S. army and navy brought in its wake. Medical social workers, hospital recreation workers and field directors in camps, supplemented by great numbers of chapter workers in home communities, constituted a closely knit network which provided invaluable assistance in the solution of individual and family problems of citizen soldiers and their dependents.

Continued expansion of the army and navy was reflected in increasing numbers of trained Red Cross personnel serving with the armed forces. By Dec. 1942 the number had increased to 5,000 and on June 30, 1945, six weeks before Japan surrendered, there were 19,508 trained Red Cross professional workers thus occupied.

As the pattern of war unfolded, the program developed. Accompanying troops in all theatres of war were field directors skilled in dealing with men. Seventy-eight Red Cross men and women were killed or died in line of duty overseas.

For the battle-weary and for men on leave, the Red Cross operated clubs, rest homes and recreation centres, such as game rooms and theatres. For the hungry it operated canteens and snack bars which served millions each month. And for the men up front, at isolated airfields and anti-aircraft posts, it operated clubmobiles. Similar to clubmobiles were the so-called trainmobiles in Iran and India which brought entertainment and recreation to the men charged with keeping the rail lines open and the flow of war goods moving.

While clubmobiles provided refreshments without charge, in accordance with a war department request, men staying in the homelike atmosphere of Red Cross clubs in leave areas and rest centres paid a nominal charge for sleeping accommodations and meals. These charges, however, never actually covered costs and, in return, the men had comfortable beds, clean sheets and towels, soap and showers and stateside meals. One of the most famous Red Cross clubs was Rainbow Corner in London, which closed its doors Jan. 8, 1946, after three and one-half years of 24-hr. service, during which more than 18,000,000 servicemen passed through its portals.

At the height of operations the Red Cross had 989 clubs, rest homes and similar installations overseas. As troops moved from one area, establishments were closed, while arrival in a new area signalled opening of new installa-

tions. Most of the 319 clubmobiles operated in Europe and North Africa, as the jungles of Pacific islands were not suited to this service.

In 1946, by agreement with the war department, the latter took over responsibility for operation of Red Cross clubs. Under this arrangement, the Red Cross continued to staff clubs with trained personnel and volunteer workers recruited from among dependents of members of the armed forces overseas, while expenses incident to operation were borne by the war department. As of Oct. 31, 1946, there were 295 such recreation facilities, 128 in the far eastern theatre, 129 in Europe and the Mediterranean area and the remainder in Alaska, Canada, Canal Zone, Puerto Rico, Newfoundland, certain Pacific islands, Greenland, Bermuda, Iceland, Labrador, the Azores and Africa.

At home the Red Cross was equally active on behalf of the armed forces as in the field. In Jan. 1941 the army and navy requested that the Red Cross establish a blood procurement program. Under this project the Red Cross operated blood donor centres in metropolitan areas and provided donors whose blood was processed into dried plasma and, as the program developed, human serum albumin, both used for transfusions. The initial request for 15,000 donations, each sufficient for one plasma unit, was shortly raised to 200,000. Following Pearl Harbor, the service expanded further, weekly donations at one time averaging 100,000. By V-J day, when the project was closed, 13,326,242 donations had been obtained in 35 Red Cross donor centres.

Late in 1945, the armed services returned to the Red Cross 1,250,000 plasma units as surplus for civilian use. This was distributed through state and territorial health departments to physicians and hospitals throughout the nation and was available without charge for the plasma itself to all who needed it. Another postwar development was distribution of gamma globulin, a by-product of the processing of human serum albumin, used in immunizing those exposed to measles and in treating those ill with this disease. Chapters were also authorized to participate in local blood donor programs when requested by recognized medical or health agencies.

Important also was the production of surgical dressings by Red Cross chapter volunteers. For manufacturers to have provided all the surgical dressings needed would have required a large expansion of manufacturing facilities, using manpower and materials vitally needed elsewhere. Because of this the Red Cross was requested to undertake its surgical dressing program. Hundreds of thousands of volunteers turned to chapter workrooms and elsewhere and, at the peak, were making as many as 3,000,000 dressings daily. Total production aggregated the staggering number of 2,481,951,637. In addition they made 61,000,000 sewn and knitted garments for distribution to civilian refugees overseas, members of the armed forces and disaster victims; more than 15,000,000 overseas kit bags, given to men as they embarked; and many other articles.

To provide sufficient nurses for the armed forces the Red Cross recruited 104,500 and referred them to the army and navy. Of these, 70,500 served. To meet the needs of civilian hospitals, it trained 215,495 volunteer nurses' aides who assisted in 2,493 hospitals, clinics and other health agencies.

Working under the supervision of medical authorities in military and naval hospitals were Red Cross professional medical social workers and recreation workers. Entertainment programs were staged by trained workers; patient participation in orchestras, theatricals, handicraft programs

and other entertainment was always stressed, but not to the exclusion of outside talent. Motion-picture programs showed the latest features an average of thrice weekly in military hospitals in the U.S. In addition to shows in recreation halls, portable projectors were taken to the wards. Up to June 30, 1946, attendance totalled 50,000,000.

Assisting professional Red Cross hospital workers in the U.S. were many trained volunteers. Members of the Hospital and Recreation corps read and wrote letters for patients, played games with them and helped stage parties at which the Red Cross Canteen corps served refreshments. They distributed books, magazines and comfort articles and in other ways helped patients to recovery. The Arts and Skills corps, composed of craftsmen accomplished in every form of artistry, taught classes in leather working, jewellery making, clay modelling, photography, painting and other subjects.

At the peak of activity, more than 3,800,000 chapter workers were enrolled in Red Cross Volunteer Special Services. In the seven years ending June 30, 1946, these volunteers contributed 978,125,929 hours of service. At the end of World War II, the following organized corps were in existence: Production, Staff Assistance, Canteen, Motor, Hospital and Recreation, Arts and Skills, Nurse's Aides, Dietitian's Aides (discontinued June 30, 1946), Home Service and Administration. In addition to duties of corps already described, Staff Assistance members performed office work necessary to keep the chapter functioning smoothly; the Canteen corps and Canteen Aides, besides working in hospitals, served at air strips, outlying posts and often on special occasions; Dietitian's Aides served in hospitals; Motor corps provided transportation for the hospitalized, for crippled children and for the chapter itself; Administration corps members directed the chapter program. Home Service corps, throughout the war, kept in touch with families of servicemen, helping with their problems. In the seven-year period ending June 30, 1946, these workers gave assistance in 17,980,000 cases.

With fighting over and the ranks of veterans swelling as never before, Red Cross volunteers expanded their programs to serve needs of ex-servicemen. To co-ordinate their activities at Veterans' administration hospitals, resident Red Cross field directors were serving in 101 such establishments during the latter half of 1946. For able-bodied veterans and dependents, chapter Home Service workers helped readjust to civilian life, aided with financial problems, advised concerning government benefits legally due them and assisted in the preparation of claims for such benefits. During the fiscal year ending June 30, 1946, Red Cross chapters financially assisted more than 161,000 veterans or their dependents.

Trained Red Cross claims service representatives at regional and other offices of the Veterans' administration assisted in filing and prosecuting claims when authorized by the veteran to do so.

Also providing for men in veterans' hospitals and those of the army and navy was Red Cross Community Service to Camps and Hospitals. Organized early in the war as Red Cross Camp and Hospital Council Service, this activity co-ordinated work of all groups and individuals in communities near camps and hospitals who desired to contribute to the welfare of men at these establishments. Requests channelled from commanding officers through

Ceiling-high stores of P.O.W. packages at one of many warehouses in neutral Switzerland used by the American Red Cross during World War II

councils to groups and individuals resulted in providing complete furnishings for 12,000 sun and day rooms, in addition to games, athletic, music and other equipment. On June 30, 1945, 223 councils and independent committees were serving 3,219 army and navy establishments and itinerant stations. More than 52,000 church groups, labour unions, fraternal orders and similar bodies through councils supplied 79,000,000 articles, from pets to golf courses.

No record of Red Cross war services would be complete without reference to what was done on behalf of prisoners of war. More than 27,000,000 food parcels, packed at Red Cross centres by volunteers, were shipped to Geneva. Thence they were distributed under auspices of the International Red Cross committee to American and Allied prisoners in axis hands. Consignments also went to the far east. Medical chests and other supplies went forward, and in anticipation of the day when prisoners would be liberated, stock piles of comfort kits containing razors, dentifrices and other articles were built up.

The Red Cross was ready to lend assistance shortly after the outbreak of war in Europe in Sept. 1939. As winter progressed, heavy clothing and other supplies went to the Red Cross societies of Rumania, Hungary, Latvia, Lithuania and other countries to help care for thousands of Poles who sought safety within their borders.

As to Poland proper, by agreement with the government general after personal inspection by an ARC delegation which travelled the length and breadth of Poland, relief was provided the stricken population. This was distributed by the Polish Red Cross and other local agencies without regard to race or creed. With Italy's entry into the war, this arrangement ceased, supplies shipped standing at approximately \$1,000,000. As war engulfed Finland, Norway, the Netherlands, Belgium, Luxembourg and France, the ARC appealed to the people for a relief fund of \$10,000,000, which a generous public soon swelled to \$22,000,000. In the same year, 1940, congress appropriated \$50,000,000, and the following year \$35,000,000 for relief "of men, women and children . . . driven from their homes or otherwise rendered sick or destitute by hostilities or invasion." The president was authorized to select agencies for distribution of this relief, and at his request the Red Cross distributed supplies purchased by government agencies.

Even while the \$22,000,000 fund was being raised, the first of several ships was chartered by the Red Cross, loaded with food, medicines and clothing, and dispatched from New York city to France, where supplies were distributed in the unoccupied area under ARC supervision. Until Nov. 1942, when the whole of France was occupied, the Red Cross continued its program, the total representing approximately \$6,000,000 in supplies.

To make relief most effective, the Red Cross applied its resources largely to selected emergency needs not met by other agencies. Only where guarantees were received that supplies would reach recipients without cost and without discrimination as to race, creed or political opinion, were relief programs undertaken. Even so, an essential proviso was that ARC representatives supervise distribution. Actual distribution in almost every case was handled through local organizations, usually the national Red Cross society. This method made possible extensive programs in many countries with limited supervisory personnel and put to use the knowledge and experience of organizations familiar with local conditions. In this process also, local agencies were strengthened and placed in better position to assist their people when the ARC program terminated.

As the war spread, ARC assistance to civilians increased. Clothing, medical and hospital supplies were sent to Great Britain. In 14 countries of the middle east from Iran to Libya, and from Egypt to southern Rhodesia, supplies valued at approximately \$3,800,000 were distributed. Bombed and destitute civilians, including 50,000 Poles in East Africa, were provided with supplemental food, clothing, medicines and sanitary supplies. Relief for civilians in Iceland, Cape Verde Islands, Portugal, Spain and Switzerland sent by and through the ARC totalled more than \$3,250,000.

To assist the soviet people, a relief program began in Sept. 1941. About \$27,000,000 worth of supplies, largely purchased by U.S. government agencies with funds from congressional appropriations, was thus distributed. Throughout the war and after, medical and other supplies went to the Chinese people. This program approximated \$10,000,000 in value, of which \$4,000,000 was flown into China from India at the height of hostilities; half that amount was delivered after fighting stopped.

As Allied armies advanced, ARC relief workers followed in their wake. With the liberation of country after country in Europe, supplementary assistance was provided to the freed populations. Milk feeding programs by which hundreds of thousands of school children received an extra half pint of milk daily were instituted. Clothing, shoes and medical supplies were distributed and several million parcels, each containing eight pounds of food originally intended for prisoners of war but declared surplus at war's end, were distributed to individuals in hospitals, institutions and displaced persons camps. Countries in Europe benefiting from postwar programs included France, Belgium, Luxembourg, the Netherlands, Norway, Finland, Greece, Poland, Yugoslavia, Czechoslovakia, Albania, Italy, Austria and Germany, where the program was largely confined to displaced persons.

The Red Cross program in the Philippines included the general civilian population, released prisoners of war and civilian internees. Following liberation the ARC sent relief supplies valued at more than \$2,000,000 to the islands. With granting of independence to the island commonwealth, ARC representatives assisted in the reconstitution of the Philippine Red Cross, formerly a chapter of the ARC, and its development into an independent society.

Supplies shipped by the Red Cross in its world-wide relief programs included complete hospital units, X-ray materials, equipment for production of blood plasma and penicillin and large quantities of soap. About 250 motor vehicles, many to make distribution of relief possible, were sent. Also included were powdered and canned milk, vitamins and other concentrates and some 41,000,000 garments made by Red Cross chapter workers.

Despite its global activities, the ARC did not slacken its domestic services. By 1937 it had developed a disaster assistance program, the roots of which were buried deep in the silt of the Ohio-Mississippi valley floods of the 1880s and the ashes of the Michigan forest fire of 1881. The 108 domestic disasters in which it gave aid during 1935-36 proved but a prelude to the Ohio-Mississippi valley flood of Jan. 1937—the greatest single flood disaster in ARC history—affecting 196 counties in 12 states. Contributions of more than \$25,000,000 flowed in to the Red Cross, enabling it to function effectively during the emergency and subsequently help refugees resume normal life. More than 1,000,000 persons received Red Cross assistance during this operation, including 97,247 families that required substantial rehabilitation aid.

During the ten-year period 1937-46, the Red Cross gave

assistance in 1,778 disasters. The number of persons assisted totalled 2,272,626 and disaster relief expenditures amounted to \$42,605,763. Disaster nurse recruitment was stressed; an outstanding accomplishment of this service was the recruitment of more than 2,000 nurses to serve in polio outbreaks during the summer of 1946.

The decade also saw intensification of other Red Cross community services. In the five months preceding Pearl Harbor the organization trained and qualified an average of 47,000 first aiders monthly. The next 14 months piled up a total of 5,500,000 certificates issued. Total number of persons trained during the decade ending June 30, 1946, aggregated 9,709,293. Instruction in swimming and water safety resulted in 3,591,069 certificates being issued during the period, while the accident prevention program was developed to the point where this Red Cross activity was well recognized.

To help offset the shortage of nurses, the Red Cross Nursing Service throughout the war emphasized particularly its long-established program of home nursing instruction. During the decade 1,872,925 men, women and young people successfully completed the course. In the field of nutrition, although the Red Cross had a well-developed program dating from the '20s, efforts were redoubled.

The American Junior Red Cross, which in 1946 numbered just less than 20,000,000 members, carried on a far-reaching program of service to members of the armed forces, to young people abroad and to their own communities. They made clothing for youngsters of war-torn lands; furnished millions of articles, games, furniture, canes and similar items, to men in camps and hospitals, and sent 1,400,000 gift boxes, each containing approximately 12 articles, to children overseas. From their National Children's fund, made up of their own contributions, they provided equipment to care for war orphans and evacuees; and, as liberation progressed, they sent large quantities of school supplies to children abroad to speed educational rehabilitation.

Consolidation of health-related Red Cross activities was effected early in 1946 under a newly-created Office for Health Services, which administered the disaster medical service and the blood donor, first aid, water safety, accident prevention, home nursing and nutrition work of the organization.

Contributions in annual Red Cross fund campaigns after Pearl Harbor aggregated \$789,151,800, including the organization's largest peacetime fund appeal, made in March 1946. The goal of \$100,000,000 was oversubscribed by total contributions of \$119,000,000. In the international field, the ARC during 1946 shifted emphasis from providing civilian relief to large masses of population, to strengthening national Red Cross societies so they might better cope with problems of relief.

At the close of 1946, the ARC comprised 3,754 chapters with 5,314 branches and an adult membership of more than 21,000,000. (H. BM.)

World-wide Activities.—The years between 1937-46 brought to the world-wide Red Cross organization disrupting pressures similar to those affecting governments but, at the same time, they afforded opportunities for humanitarian service by Red Cross organizations beyond any other decade in their 80-year history. The efforts of national Red Cross societies and their international organizations to meet the challenge of broad-scale human suffering during these years brought added prestige to the Red Cross throughout the world.

The war in Spain as the decade opened offered a prototype of both the disintegrating pressures and the opportu-

nities for service. Reflecting the split in the government, the Spanish Red Cross was divided into two organizations, both carrying on Red Cross services on their respective sides of the battle lines. On the other hand, through the International Red Cross committee, help from Red Cross organizations outside of Spain and from other agencies was administered to the victims of that war. The total outside relief administered in Spain by the International committee was valued at approximately \$450,000, divided practically equally between the two sides.

When war struck in China in 1937, Red Cross societies made substantial contributions to Chinese relief. The Chinese Red Cross was not a strong society, and much of the relief was administered through committees organized for that purpose in China. As the war continued, the Chinese Red Cross became more closely integrated with the medical service of the Chinese army and near the end of the conflict was operating 60 mobile medical teams. Plans for the reorganization of the Chinese Red Cross designed to strengthen the national organization and carry through a wider program of civilian service were underway in 1946.

Late in the 1930s, Hitler abolished the Junior Red Cross in Germany as Mussolini had done earlier in Italy. The adult Red Cross organizations in both countries directed their programs to services designed to supplement the medical services of the armies and, particularly in Germany, to assist in caring for wartime civilian casualties. Nursing services and training were intensified, and training programs for first aid to the wounded were promoted. During the war, the Red Cross societies in both Germany and Italy trained nurses, operated ambulance and hospital units and provided medical supplies and personnel to supplement the armies' resources. In addition, they operated information bureaus for prisoners of war, cared for civilian homeless and handled messages and inquiries for the civilian population. In 1943 and 1944, units of the Italian Red Cross in Allied territory aided Allied military government in meeting the health and welfare needs of civilians. A demilitarized Italian Red Cross was functioning throughout Italy and expanding its civilian services at the end of 1946. The German Red Cross, however, had been dissolved as a national organization in May 1945, although units were subsequently permitted to function on the *Land* level in the U.S., British and French zones.

The complete occupation of Poland by Germany and the U.S.S.R. in 1939 and the establishment of a Polish government-in-exile provided another manifestation of the disrupting forces affecting Red Cross organizations during the war years. Remnants of the Polish Red Cross continued to function in Poland, furnishing relief to the civilian population, operating hospitals and clinics and handling messages and inquiries. Within a short time, however, there was established in connection with the Polish government in London a Polish Red Cross committee directing particular attention to Polish refugees outside the occupied area. This pattern of split Red Cross organizations characterized other occupied nations; e.g., Yugoslavia, Greece, France, Norway and the Netherlands. In 1945, committees of the Red Cross societies of the Baltic states came into existence in western Europe, working on behalf of refugees from Lithuania, Latvia and Estonia, whereas the national Red Cross societies in those countries were considered by the soviet authorities as having been incorporated into the national Red Cross and Red Crescent¹

¹In Moslem countries, voluntary organizations formed under the terms of the Geneva Red Cross convention became known as Red Crescent rather than Red Cross societies. In Iran, the society was named the Red Lion and Sun.

organization of the soviet union.

The Union of Red Cross and Red Crescent Societies of the U.S.S.R., a federation of the societies in the various republics of that nation, worked closely with the commissariat of public health throughout the war period. In addition to the training of teams to care for the civilian and military wounded, the organization operated civilian hospitals, orphanages and homes for the blind. It rapidly expanded its nursing service and embarked, late in 1944, on an extensive civilian public health program, establishing 10,000 nursing centres in the devastated areas of the western U.S.S.R. The organization served as the principal agency in the soviet union to receive and distribute relief sent to the U.S.S.R. by foreign agencies.

The British Red Cross, at the outbreak of the war in 1939, formed together with the Order of St. John of Jerusalem a war organization to conduct Red Cross activities. During the air raids and robot bombings, the organization operated first aid stations and furnished medical supplies and equipment for the treatment of casualties. In addition to carrying out other traditional services of the Red Cross, the British Red Cross organized relief for British (and empire) prisoners of war and sent through the International Red Cross committee large shipments of food, clothing and medical supplies for prisoners of war. The Red Cross societies of the other parts of the empire similarly made substantial contributions for the relief of prisoners of war. Most of the food packages made available during the last years of the war were packed by the Canadian and American Red Cross societies, whose volunteers worked long hours on factory-type assembly lines in packing plants to prepare the parcels distributed to Allied prisoners in Europe and the far east. The programs of the Red Cross societies in Australia, New Zealand, the Union of South Africa and Canada included not only health and related services to their own populations, but also extensive assistance to civilian war victims in England and in other war-torn countries.

In the far east, the end of 1946 found the Japanese Red Cross refocusing its program under the direction of the occupying forces with the advice of representatives of the ARC. In the U.S. zone of Korea, a newly formed Korean Red Cross had replaced the branch of the Japanese Red Cross formerly established there. American Red Cross representatives were assisting military government in this and related tasks. The chapter of the ARC in the Philippines was progressing rapidly toward independent status as a national Red Cross society for the islands. As for the American Red Cross itself, the war years brought the greatest expansion in its history (see above).

The activities of all of the 61 Red Cross and Red Crescent societies of the world reflected the war conditions of the period. The societies of neutral nations such as Switzerland, Sweden and Eire (formed in 1938) engaged in extensive foreign relief work and in the care of refugees in their countries.

The League of Red Cross Societies, a federation of the Red Cross and Red Crescent societies of the world, continued during the war period to serve as a clearinghouse for information among the societies and helped promote Red Cross service programs. A convention of Red Cross societies called by the league at Oxford, Eng., in July 1946, helped formulate continuing national and international programs for Red Cross organizations.

The International Red Cross committee—an independent organization of 25 Swiss citizens established in 1863,

and recognized by governments as a neutral humanitarian agency—performed throughout the decade many diverse services on behalf of prisoners and civilians. In addition to its help to war prisoners (see PRISONERS OF WAR), the committee handled approximately 24,000,000 civilian messages (through July 1946), joined with the League of Red Cross Societies in the distribution of relief supplies to civilians through their Joint Relief commission, and generally endeavoured to keep alive humanitarian concepts in a world torn by war.

Only one International Red Cross conference—scheduled every four years to bring together the national societies, their international organizations and representatives of governments—was held during the decade. It was held in London in 1938. The 1942 and 1946 conferences could not be convened. Plans were initiated in 1946 to have the next meeting at Stockholm, Sweden, in 1948.

Reece, Brazilla Carroll

Reece (1889–), U.S. politician and lawyer, was born Dec. 22, 1889, in Butler, Tenn. The son of a farmer, he was one of 13 children. He was graduated from Carson and Newman college in Tennessee with a B.A. degree (1914); he also studied at New York university, where he received his M.A. degree in 1916. He enlisted in the U.S. army in May 1917, won a commission and rose to battalion commander in the A.E.F. Cited for heroism in action, he won the distinguished service medal, the distinguished service cross and the croix de guerre (with palm). After studying at the University of London (1918–19), he returned to the U.S., becoming instructor of economics at New York university. He left after one term, however, to run for the U.S. house of representatives as Republican candidate from Tennessee (first district).

Elected to congress in 1920, he served until 1946, save for the 1931–33 term when he was defeated. A consistent opponent of the New Deal administration's domestic and foreign policy, he was selected as chairman of the Republican national committee on April 1, 1946. His victory was hailed as a triumph for midwest Republicans over Stassen proponents in the G.O.P. He resigned his seat in congress to take up his new post.

Reed, Stanley Forman

Reed (1884–), U.S. jurist, was born Dec. 31, 1884, in Mason county, Ky. He was graduated from Kentucky Wesleyan college with an A.B. degree (1902) and from Yale university (1906). After studying law at the University of Virginia, Columbia university and the Université de Paris, he returned to Kentucky, practising in Maysville and Ashland (1910–29). In 1929 Pres. Hoover appointed him general counsel of the old Federal Farm board, a post he held until 1932, when the president transferred him to the Reconstruction Finance corporation in the same capacity.

In March 1935 Pres. Roosevelt named Reed solicitor general of the U.S., and on Jan. 15, 1938, the president appointed him to the supreme court as associate justice. This appointment was unique in that it received publicly voiced approval from spokesmen of both major political parties. He was sworn in Jan. 31, 1938. Justice Reed gen-

erally voted with the court's liberal majority and in 1944, he wrote the majority decision, announced April 3, that Negroes could not be barred from voting in the Texas Democratic primaries, rejecting the thesis that political parties were private associations and therefore exempt from constitutional regulation.

Rehabilitation of the Disabled

Paradoxical as it seems, war brings mankind certain benefits. This was graphically illustrated during World War II by the rapid advances made in the fields of physical medicine, occupational therapy and rehabilitation. Early in World War II, a leading orthopaedist predicted that whereas World War I had advanced orthopaedics as a recognized specialty, World War II would do likewise for physical medicine. A survey of the advances made in physical medicine indicates that this prediction was fulfilled. Not only had the war years brought new technological advances and treatment techniques; they had seen the development of an almost entirely new philosophy in the use of physical medicine and occupational therapy.

Prior to World War II, physical medicine and occupational therapy were thought of by most practitioners as specific procedures designed to restore function or strength to specific afflicted parts. When a patient was admitted to the hospital for a leg fracture, treatment was too often confined solely to the injured leg with little regard for the over-all physical or psychological condition of the patient. The injured leg healed, but the general physical condition of the patient deteriorated. He was restless and frequently excessively bored with the routine and inanity of hospital life.

This situation was particularly acute in military hospitals at the outset of World War II. In order to convert hitherto wasted convalescent time into useful, purposeful activity, the military services inaugurated convalescent programs designed to send the soldier-patient back to military duty in the best possible physical condition in the shortest possible time and to give him instruction which would make him a more effective fighting man. Physical activity and military education became as much a doctor's prescription as drugs and diet. Muscles were not permitted to atrophy, for reconditioning and physical therapy started the moment the acute illness of surgery terminated. Minds did not become stagnant, for time was spent purposefully. Hospitals were transformed into a combination gymnasium, school room, machine shop and summer recreation camp.

The emphasis in these programs was placed on functional training. Beading looms and fancy work were replaced by carburetors, radio equipment and engine parts. Men practised radio code while in bed. Military training aids, visual aids and handicrafts along with model aero-

Machine shop at the Birmingham General hospital, Van Nuys, Calif., in 1944, where convalescent veterans were being prepared to find a place in civilian life. These men received compensation on an off-duty basis during the retraining program

planes, tanks, ships and camouflage nets were educational as well as therapeutic devices. The tools of war and industry were substituted for the basketwork type of diversional occupational therapy.

To meet the needs of combat veterans suffering from serious physical and psychological wounds, special convalescent hospitals were activated where rehabilitation programs could be broadened to meet the needs of the "whole man," whatever they might be. Intensive programs of physical reconditioning, educational training, psychological readjustment, resocialization and vocational guidance were tailored to meet the needs of each man as an individual. This philosophy was to "treat men, not diseases."

Special programs were established in military hospitals for particular disabilities. Major amputation cases were not only given physical and occupational therapy to toughen stumps, increase circulation and prevent atrophy and limitation of motion, but were taught to use their prosthetic devices. Self-care particularly was stressed in order that artificial arms and legs could be used effectively. Men were taught to apply and remove their own appliances, climb in and out of automobiles and busses, drive specially fitted or stock model automobiles, remove coins from a purse, unlock doors, dress themselves and relearn the thousands of simple tasks necessary to carry on daily life. It was recognized that fitting a man with an artificial appliance represented only one part of treatment, and that training the individual to use the appliance efficiently was equally important.

Extensive research programs were started with engineers, orthopaedists, limbmakers and technicians pooling their knowledge to attempt to improve the design and function of artificial appliances. Real improvements on both artificial arms and legs were made.

Particularly dramatic were the advances made in the care and treatment of men suffering from spinal cord injuries which left them paralyzed in the lower extremities. Although there were notable exceptions, the life expectancy of such victims previously had averaged about two years. Practically all cases were bedfast or confined to wheelchairs. Death usually came from some type of infection, ordinarily of the kidneys. With the discovery of sulfa drugs, penicillin and streptomycin, infections could be controlled. It was estimated that 80% of the 2,300 U.S. cases resulting from World War II learned or were learning to live independent lives with their braces and crutches. Trained by physical and occupational therapists, they learned to apply and remove their own braces, get in and out of bed, dress themselves, climb stairs, get up and down curbs, cross streets within the time of the traffic lights and take care of their personal needs.

Occupational therapy, particularly, played an important role in the special centres which the military services established for the blind. In these centres, emphasis was placed on independence, self-care, the ability to travel alone, development of confidence, vocational guidance and prevocational training.

Both physical and occupational therapy were an integral part of the treatment of neuropsychiatric patients. Physical reconditioning, recreational therapy, athletics, handicrafts and educational activities were used as adjunctives to definite psychiatric care. Supplementing individual and group psychotherapy, such activities aided patients in regaining lost perspectives and confidence and re-establishing desirable attitudes, habits and values. Physical therapy through exercise, continuous flow baths and wet packs was widely used with psychotic patients.

In some military hospitals, industrial therapy projects were started whereby patients while still hospitalized were able to spend a portion of each day doing piece work and

Men of the U.S. army air forces harvesting rhubarb in 1944 while convalescing at a hospital in Pawling, N.Y. Work on the hospital's 700 acres of land was volunteered by patients, 90% of whom returned to active duty

subassembly work for near-by industrial plants and receiving pay for their efforts. In the majority of hospitals, however, work therapy was limited to clerical work, food services, ward duties and maintenance work for the hospital itself. "On the job" training for a limited number of hours each day provided vocational training in both military and civilian skills as well as short work experiences which could be used in determining interest and aptitudes for vocational guidance. Definite plans were made by the military services to make the wartime innovations in physical medicine, occupational therapy and rehabilitation a permanent part of the peacetime military hospitalization programs.

The philosophy, concepts and many of the techniques developed by the military services were carried over into the hospitals caring for veterans. Although veterans' hospitals had both physical and occupational therapy prior to World War II, such programs were very limited. In some cases, occupational therapy was conducted for the benefit of the hospital rather than the patient. Men shovelled coal, cut grass and repaired furniture. This was known as "work therapy," but the primary emphasis was on the "work" with not too much regard for the "therapy." Such hospitals now provided well-rounded programs of physical and occupational therapy, physical rehabilitation, vocational training and education, with special divisions for patients with spinal cord injuries, blind patients and those who had suffered hearing losses. Staffs composed of physical medicine specialists, physical therapists, occupational therapists, physical educators and teachers were assigned to all hospitals. The purpose of the programs was to bridge the gap between the bed and the job by keeping the rehabilitation process continuous and uninterrupted from the time the man was wounded or injured until he was able to return to society as a self-sustaining citizen.

Added impetus to the field of physical medicine and occupational therapy during the war years came from the Baruch Committee on Physical Medicine, established in 1944 in the United States to further research and training in this field. Financial grants were made by the committee to establish three major physical medicine centres. One of the centres was to be a model in which all phases of physical medicine, including physical and occupational therapy, electronics, hydrology, climatology, manipulative procedures and physical rehabilitation could be developed. Another centre was to specialize in hydrology, climatology and spa therapy with the third devoting its major attention to the preventative and manipulative aspects of the structural mechanics of the body. Other projects included research in electronics and biophysics, the psychologic aspects of physical medicine, structural effects of changes of temperature on the neuromuscular apparatus, the effectiveness of thermogenic agents on deep tissues and similar technical studies.

The committee provided a number of fellowships in physical medicine and made studies translating the rehabilitation experience of the military services into its applications for civilian use.

The utilization of the science of physics therapeutically previously had been minimal as compared with the use of the science of chemistry. This was largely caused by the fact that physical medicine is usually nonspecific in action; it helps the patient recover, but is most often an adjunctive rather than a primary agent of treatment. The development of new diagnostic devices such as the electronic stethoscope, the electro-encephalograph and the psychogalvanic reflexometer and the new therapeutic devices of microwave high frequency apparatus, electric shock therapy equipment and apparatus for electronarcosis opened new

Pottery work, in a Red Cross workshop, by a convalescent soldier at the Halloran General hospital, Staten Island, N.Y.

vistas for the physiatrists—the designation adopted in the United States to describe the physician specializing in physical medicine. The links between general medical treatment and physical medicine were strengthened by clinical work in fever-chemotherapy and in ion transfer.

There was little doubt that in the development of atomic energy for peacetime use, one of its most significant contributions would be in the field of physical medicine. During World War II the newer concepts of physical medicine, occupational therapy and rehabilitation saw the art of medicine welded inextricably to the science. Technological strides provided new diagnostic and treatment measures, but the basic law of good medicine itself had a renaissance of equal importance. Scientific advances were made without sacrificing the ideal that in physical medicine the doctor should treat patients as well as diseases. The basis for such care was not only diagnosis and treatment, but development by the patient of his own potentialities. (See also MILITARY MEDICINE; PSYCHIATRY.)

Reichenau, Walter von

Reichenau (1884-1942?), Germany army officer, was born in Karlsruhe, son of an army general. He joined an artillery unit in 1903. During World War I, he served on the German general staff and in the early days of the nazi

regime was regarded as one of Hitler's favourites. He was raised to the rank of a lieutenant general during the Polish campaign in 1939 and was made a field marshal in July 1940 in recognition of his generalship in the French campaign a month earlier. Marshal von Reichenau was in command of the army that scored initial successes against Marshal Budenny's soviet forces in the Ukraine campaign in the fall of 1941. In Nov. 1941, however, his armies met defeat at the hands of Marshal Timoshenko and he was driven out of Rostov. A Berne dispatch of Jan. 17, 1942, said Marshal von Reichenau had died of apoplexy while travelling back to Germany "for reasons of health."

Relief

During the decade 1937-46, the entire field of relief entirely reversed itself, from measures designed to grapple with the widespread spectre of unemployment which had terrified the world during the 1930s, to its entire disappearance in 1940, not by reason of any of the measures taken to handle it, but because World War II absorbed all available manpower and created a deficit of workers in place of the deficit of jobs which had prevailed. Relief, once more, was demonstrated to be a mitigation but not a treatment, much less a cure of the evil of unemployment.

Unemployment.—Comprehensive plans for handling the problems of unemployment by means of relief had been only tentatively approached. Great Britain had experimented after 1920 with an effort to include all the unemployed within the pattern of social insurance, and in 1934 acknowledged its failure by separating insurance, by reserving to insurance the contractual benefits for the unemployed entitled to them, and by placing on relief all workers, willing but unable to secure work, who were not eligible for insurance or had exhausted its benefits. The United States in 1935 had passed the Social Security act affording a limited protection for the unemployed by social insurance, but made cautious by Britain's experience of stretching the coverage of insurance too thin, made no provision for the rest of those involuntarily out of work. No other English speaking nation had made any effort by the end of 1936 to grapple with the problem of unemployment through social insurance.

Relief to the unemployed had little precedent in English speaking countries. The idea of the able bodied receiving assistance without work sounded, in the thrifty thinking of the Anglo-Saxon, too much like putting a premium on idleness. It was, in addition, a very expensive way to handle the support of the unemployed, in view of their number and the indefinite continuance of their worklessness. Again, Anglo-Saxon tradition placed the relief of its poor upon the locality in which they lived. This tradition had persisted for at least three centuries and was firmly embedded in law and judicial decision. But unemployment was not a local phenomenon; nothing done by a locality or its people caused it or could cure it. Its national nature seemed to indicate a national approach to its treatment. These considerations led all the countries during the decade 1937-46 to modify or discard the tradition of local responsibility for local need, either by the state assuming the entire responsibility for the relief of the unemployed, as Great Britain did, or by the state offering "grants-in-aid" to local governments for that purpose, as did Canada, Australia and New Zealand. In the United States, where the

conservative forces were strong enough to block any permanent and comprehensive plan for the care of the unemployed, the federal government undertook to care for certain of the unemployed at national expense. However, eligibility was measured by the means test.

There was a wide disparity of opinion as to the way the unemployed should be helped. Under the vigorous and all but universal tradition that the able bodied should work for their living, all countries except Great Britain provided artificially created work for them. (This method of "made work" was also employed by the western European powers in the same period.) In Great Britain it was claimed that "made work" was artificial and likely to turn out to be useless, after completion. It therefore, under the Unemployment Assistance board, treated the whole problem as one of relief on a national scale and with a national administration. Avoiding the acceptance of the unemployed as a uniform problem, the board studied the personnel of those under its responsibility, the length of time they were dependent, where they lived, their age, their working experience, if any. It attempted to break the mass into separate classes, each calling for different treatment.

The more promising and younger were given six months vocational training at public expense and thereafter had little difficulty in finding employment. The more ambitious were removed from the "derelict districts" from which industry had disappeared and placed in more favourable industrial localities where jobs could be had. The government subsidized self-activity projects started by the Society of Friends and taken up in several towns and parishes, whereby the unemployed undertook local improvements such as making parks and play spaces out of waste land or supplying services for local purposes, such as guides to the blind, readers to shut-ins. This movement, which added no income to the unemployed but restored their esteem in the eyes of their fellow townsmen, spread all over Great Britain, except the metropolitan centres, in the short time between its inauguration about 1935 and the end of unemployment in 1939. The board determined by research that although the total number of the unemployed rose at times (such as 1935) to more than 2,000,000, three quarters of the total were only temporarily without work; about 500,000 constituted the "hard core" of the unemployed, many of whom had not worked at all. Predictions, however, on their uselessness were proved false, for the war absorbed all of them in the military services or in industry. The same dire predictions were made at least in Canada and in the United States and were also demonstrated as fallacious.

In the countries which adopted "work relief" as a means of aiding the unemployed, the questions of choice of work presented some difficulties which proved insoluble, especially if it were assumed that such projects must not compete with private industry. The first project—raking leaves, selling a surplus of apples on the street corners—brought the whole plan into disrepute, and finally the state undertook such public improvements as were needed but could not be financed locally, irrespective of the possibility of doing them under contract with private contractors. In the United States, also, there was a wide diversification of projects, such as research, creative and historical writing, dramatics and general recreational projects. In spite of the obvious advantage of using the unemployed in a way best fitted to conserve their skill and to serve their localities, these skilled and unusual methods of spending public

money on the unemployed provoked a good deal of opposition which compelled abandonment of many of them.

Another question which had been a nightmare to local relief administration was care of the transient. In periods of unemployment this had become a critical issue, for casual labour drifted to urban centres when out of work. The central government of Canada and the United States met this difficulty by financing entirely their care during the depression; but the problem still remained unsolved.

In the United States, the Federal Works Progress administration assumed entire responsibility for the treatment of the unemployed in 1935. During its existence to 1940, it furnished employment to about 8,000,000 persons and paid them more than \$9,000,000,000. There was no such effort to break down the mass of the unemployed into understandable units as in England, and some resistance arose in public opinion to diversify the jobs, as stated above. The only action in this direction was a negative one: congress, quick to sense articulate public criticism, passed a bill in 1936 removing from the rolls all who had been on them for 18 months or more, and made them ineligible for re-employment for 6 months.

Social Insurance.—During the decade, Canada and the United States were freed from constitutional restraint on federal action in the field of social welfare. The privy

Householders receiving relief rations of oranges, apples and rice in Cleveland, Ohio, where thousands applied for food during the "recession" of 1938

council in London, acting as supreme court, had ruled that the articles of confederation of Canada did not enable its federal government to enact a social insurance law for the entire dominion, but this disability was avoided by the device of grants-in-aid to the provinces. In the United States, it was tacitly understood that although it was specifically stated in the constitution that the purpose in establishing the government was (among other objectives) to promote the general welfare, "general welfare" did not authorize the federal government to enter the field of social welfare, traditionally a local function, but only to promote the welfare of the states in their relation to each other. Pres. Pierce in 1854 expressed that opinion in vetoing a bill to authorize the federal government to grant aid to the state in the task of caring for the insane. However, the supreme court, in a seven to two decision, given by Judge Benjamin Cardozo, upheld the old-age insurance provision of the Social Security act in May 1937, stating that "the problem is plainly national in area and dimension" and the act was "conducive to the general welfare."

During the first years of the decade 1937-46, other phases of relief were left by the several countries to a non-integrated series of provisions, adopted at different times and under varying influences. Provisions for old age were most prominent, with powerful political backing. Two sections of the Social Security act of the United States, one for social insurance, amended to include survivors in 1939, and one for assistance, grew to be the most important peacetime function of the U.S. government in point of volume. New Zealand, whose original provision for old age was made in 1898, and Australia, whose action dated back to 1908, continued to liberalize their laws. Great Britain authorized the Unemployment Assistance board (with name changed to Assistance board) to grant supplementary allowances to recipients of old-age benefits when it could be shown that the benefit was inadequate to maintain the beneficiary. This had previously been granted by the local poor boards.

Assistance to families with children whose breadwinner was dead, sick or otherwise unable to provide for them had been in effect after early in the century in all English-speaking countries except South Africa, and during the decade under review had been liberalized by increased allowances and broader scope, generally by the federal authority contributing a larger portion of the grant.

For the chronically and acutely sick, the story in the different countries varied widely. In the United States, there was no provision for either except for the blind, outside of poor relief, financed under the utterly unpredictable policy of local authorities. The very strong opposition to the federal government's entering this field blocked all efforts to enact a health insurance law or to provide for general health services. In all other countries, sickness and permanent invalidity were financed by the social insurances, generally recognized to be the most satisfactory and economical of all the forms of social insurance.

In 1938, New Zealand, by the passage of its Social Security act, broke entirely new ground by creating an all-inclusive pattern for its social services, including both social insurance and public assistance. Sir William Beveridge proposed an all-inclusive plan for Great Britain in 1942, but it was implemented only piecemeal and not as an integrated entity. Social insurance was still separated from public assistance, although the general trend was toward centralizing the administration of public assistance in the Assistance board and removing it from local poor law officials. The proponents of the Social Security act in the United States had hoped to secure an integrated, if

not a unified, program for the social services; but the final result was nine separate and wholly unrelated acts, some in public assistance, some in general welfare, some in social insurance, and leaving wide areas of need untouched.

New Zealand discarded the distinction of social insurance by making eligibility for any of its benefits independent of specific payments into the fund. Every wage earner paid 5% of his wages (plus a small registration fee semi-annually into the fund). Any deficit was made up by appropriations from the general revenue, which amounted to about one half its total expenditure. For this payment, a citizen of New Zealand was entitled to receive the following benefits without reference to any other source of income: the survivors of a wage earner could receive support during their minority and the widow until remarriage, the unemployed were entitled to specific allowances; the totally incapacitated were cared for during invalidity; the sick received medicine, medical and nursing services and hospital care; maternity benefits were made available, including two weeks of nursing service, hospital and medicinal care; old-age benefits beginning at 60 years of age; and if the commission found need not defined under the above descriptions, it was authorized to afford such assistance as necessary. In reality this was a co-operative venture on the part of the state and its citizens, whereby the state agreed to protect the citizen from economic need in return for a flat contribution geared to his ability to pay and to his need. This act was passed by the Labour party when it took over in 1938, and while it was in substance merely the continuance and liberalization of separate provisions previously adopted, its integration into a single system and its extension to cover all citizens without the means test was largely new. Observers said that it was considered an economically dangerous project by the more conservative citizens in New Zealand, and that it had become the subject of political conflict between the party in power and the older conservative group.

A new development in the field of social welfare was the so-called family allowance provision. Some economists had long urged that in a wage system such as conducted by modern industry, some provision should be made whereby marriage and children might not be economic handicaps. Four countries passed acts granting bonuses to families on the birth of children: Great Britain in 1945, Canada in 1944, Australia in 1941 and New Zealand in 1938. The amount given per child varied between countries; some did not grant an allowance for the first child; some graduated the amount per child, inversely to the number of children; but all granted them without reference to other income in the family.

Aid for Soldiers.—In the change effected in the economy of each belligerent, the entire pattern of welfare was altered by World War II. A few nations such as Australia strengthened regular assistance, including invalidity, old-age and maternity benefits, as war measures, but emphasis generally shifted from unemployment and other peacetime problems to measures to make good to families of servicemen (and servicewomen) the loss of income caused by enlistment of the breadwinner. The pattern for such provisions was pretty well laid during World War I and was followed without much change. In general, the allowances were increased in amounts, but the conditions under which they were given remained identical with those laid down in the Soldiers' and Sailors' Insurance and Allowance act drawn up for the United States by Judge Julian W. Mack in 1917, based on the experiences of the bel-

ligerent countries from 1914 to 1917. For wife and children, the enlisted man had to make an allotment from his pay, to be sent to his family. The government then added an amount graduated to the number of children if married and a flat amount, if a wife alone. It was not necessary in any of the countries under review for the man to have had a history of supporting wife and children, or that they have no other income. In some countries, illegitimate children were included in the provision for the benefits. It was clearly the intent of all Anglo-Saxon countries to provide some allowance for all who normally had a claim by marriage or birth upon the enlisted man's support, but not to inquire too vigorously into his previous habits in that regard.

With respect to others accustomed to look to the enlisted man for partial or entire support, the plan was somewhat different. As in the case of a wife, the enlisted man made an allotment from his pay; if already sending an allotment to a wife, the secondary allotment would be smaller in amount; in this case it was also necessary to show that he had contributed to the support of such relatives before enlistment, and the amount granted by the government was usually less per person than to a wife, and a total maximum was set, in most countries, to the government allowance. Beneficiaries were limited to parents (no country apparently made provisions for grandparents), brothers and sisters and grandchildren. The United States also offered enlisted men term insurance on their lives up to \$10,000 by assuming the cost of the extra occupational risk.

Generous provisions were made by all countries for the demobilized service men, including medical and hospital care, vocational training and fitting for vocational usefulness; most countries also granted disability pensions graduated according to severity of the handicap.

For the soldier on separation from the army, extensive provisions were made to compensate so far as possible for his loss of opportunity to earn during his years in service. Several countries granted a separation allowance (the United States of America); or transportation to their homes (Australia, New Zealand); most of them guaranteed that the discharged man could have his old job back and on the same conditions as if he had never left it (Canada, New Zealand, the United States); two (Australia and the United States) granted him support for a specified time depending on length of service; other countries (Canada, Great Britain and New Zealand) accepted his term of service as the equivalent of contributions to the unemployment insurance of from six months to a year. In addition to providing free medical and hospital service to the injured serviceman, at least Canada and the United States were making extensive provisions to furnish free hospital service to any discharged soldier whether or not the illness could be traced to his service. All countries under review made some provisions for loans to former servicemen. That of the United States was the least generous, offering merely to guarantee half of a loan secured from a finance company up to \$4,000, another evidence of the reluctance of that government to enter into competition with private business. Some countries loaned various sums for different purposes: New Zealand would loan up to £50 without interest and as much as £3,500 at low interest to enable the former soldier to purchase a farm.

It was in the field of education, however, that the most generous provisions were made. The United States led in this respect, offering as much as four years of grants for education, covering tuition and a maintenance allowance.

Canada offered less specific benefits, but on account of the ease of communication between the two countries it was likely that its provisions ultimately would not differ materially from those of the United States. Religion

Exceptional and continuous stress throughout the decade 1937-46 was put upon evangelism, which was distinguished from its earlier forms by stressing the relevance of religion for the times and the need of corporate repentance and Christian conduct. Extensive interdenominational preaching missions were conducted each year, in addition to the separate efforts of denominations and single parishes. Experts in economic and social relationships were included in the evangelistic teams. Parallel efforts were specifically directed to particular groups, such as university faculties and students, teachers, ministers and the armed services. Series of "religion and life" weeks in Great Britain were similar to the evangelistic campaigns in the United States. Much of the evangelistic preaching of the decade, particularly during the war period, took place outside of churches, both to the armed services and to civilians attached to temporary industrial communities. Temporarily, at least, the methods of the church were greatly unstiffened. The most spectacular of mass evangelism efforts were those of the Roman Catholic Church in its great outdoor Eucharistic celebrations and the "Youth for Christ" campaign supported in many cities by the more fundamentalistic types of churches.

In 1945-46, the largest Protestant body, the Methodist Church, climaxed its postwar effort by a universal campaign of evangelism culminating in a permanent "New Life Movement."

The Church in Civilization's Crisis.—The sense of the church's responsibility for the moral guidance of civilization was expressed during the decade in the notable papal pronouncements and, particularly for Protestant and Eastern Orthodox bodies, in the Oxford World conference in 1937 on the church, community and state. The reality of the church as a universal society above the separate national communities was most concretely expressed in the organization of the World Council of Churches, in the maintenance of connection between churches of belligerent countries throughout the war, and in the partially effective effort to consolidate world-wide Christian attitudes with respect to the conditions of a durable peace as well as by vast provision of material aid in the period of

postwar rehabilitation. Even with the handicap of the imperfection of its own life and membership, the church increasingly expected to influence the course of society. Types of religion which previously had held aloof from political and social action as foreign to religion concurred in this "activist" attitude.

Missions.—The Madras, India, conference held early in the decade and attended by equal numbers of oriental and western delegates, was the most significant world-wide missionary gathering of modern times. Its distinctive ideas were (1) that the thought forms and the external practices of the Christianity of each people should reflect and express that people's distinctive culture; (2) that the mission-founded ("younger") churches were to be less dependent on foreign leadership and support and (3) that they must be freed from the necessity of continuing alien sectarian differences imposed upon them by their western teachers of religion. This situation, particularly in the orient, had not sufficiently cleared by the end of the decade to permit full appraisal of the results of World War II upon the church. The Christian institutions of eastern China escaped by migration for thousands of miles into the unconquered territory of the west. In occupied zones local churches generally continued, though in forced conformity to totalitarian controls. Meanwhile, however, the "orphaned" missions, both of the belligerent, the conquered and the otherwise isolated nations, cut off from their ordinary sources of support by the war, were continuously maintained through the co-operation of international Christian agencies. Between 1939 and 1945 nearly \$5,000,000 was raised for this purpose.

Religious Education.—Reflecting in part the reduced child population of the nation, the decade registered a very general and alarming decline in Sunday school enrolment, partially balanced by the development of supplementary methods of religious education, such as daily vacation schools, carried on by the majority of churches in many towns and cities, and by extensive though unevenly distributed processes of week-day religious education most generally upon released public school time. Los Angeles, for example, enrolled approximately 150,000 Protestant children and youth in such courses. Adult forums for the discussion of Christian faith and principles in their bearings upon social and national problems had increasing vogue, and the study interests of women's groups became broader in scope. Dissatisfaction with the results of previous methods led to radical experiments at popularization of religious materials. Thus a cartoon series on the Bible, patterned after the popular newspaper "funnies," was developed.

Pastoral Ministries.—Important developments provided the churches with greater skills in the exercise of the pastoral office and increasing technical expertness in personal counselling.

A substantial and scientifically recognized literature was created on religion as intimately related to health and the integration of personality. Considerable numbers of the clergy—including chaplains in the armed forces and in institutions—became increasingly competent in diagnosis of personality problems.

The Bible.—The Bible continued to be the world's best seller. For the first time in history its production was rationed, on account of the paper shortage during World War II. The wartime destruction of printed matter caused an enormous postwar demand for Bibles as an aid to the cultural rehabilitation of the world. In 1938 a Roman Catholic revision of the Douai New Testament was published, and in 1946 the Protestant revision by a distin-

guished group of scholars of the American Standard New Testament appeared. Both sought to assimilate the new Testament to contemporary speech. The Protestant revision attempted at the same time to retain the older literary qualities of the King James version as one of the main fountainheads of the English tongue.

Personal Religion.—The decade saw a vast production and consumption of literature dealing with the cultivation of the inner life. The Methodist devotional quarterly, *The Upper Room*, for example reached an annual circulation of more than 8,000,000. A steady stream of books, such as Dr. George Buttrick's *Prayer* (1942), enjoyed wide popular use, along with republications of some of the mystical classics and interpretations of the lives of the saints. "Retreats" for the intensive cultivation of the devotional life became customary among the clergy, women's groups, and Christian youth, and in the "Ashrams" imported by Dr. E. Stanley Jones and others from India.

Public Worship.—The worship of the churches became more liturgical, as shown in the publication by numerous denominations of new service books, such as the new Methodist Book of Worship (1945). Wider use was made of the seasons of the Christian year, particularly Lent and Holy Week. More sources of liturgical material were drawn upon by Protestants. Church architecture became more dignified and more carefully designed as a setting for worship. Gowns in the pulpit and choir loft were much more frequent than formerly.

Theology.—In the Protestant religious world, theology unquestionably was taken more seriously in the decade 1937-46 than for many years. Promising groups of young theologians produced creative work in the educational centres of the east, in Chicago and on the Pacific coast. A great shift of thinking on the part of influential U.S. leaders was evidenced by a series of articles in the *Christian Century* (1946) on "How My Mind Has Changed in This Decade." There was a revolt from the previously dominant liberalism, largely through continental influences, notably the writings of Karl Barth and Emil Brunner. In contrast with trust in human reason, theology of this type called for a "God-centred" faith, stressing the sovereignty of God, His strange and inexplicable ways, and the complete dependence of man on His grace and self-revelation. The disorders of the contemporary world were widely understood as divine judgments upon the sinfulness and stupidity of man. The most extreme views went on to see in the disasters of the war period and the threatened atomic wholesale destruction of humanity portents of the literal end of human history. A "newer liberalism," on the other hand, though inclined to accept correction by profounder and more tragic insights into the reality of evil, declined to deny all capacity or dignity to human reason. The Roman Catholic theological line continued to be essentially rationalistic, and many theologians, both Catholic and Protestant, sought to reinstate the idea of a universally valid natural law, harmonious with revelation, as a ground for adjustments between competing classes and nations and an authoritative basis for a world morality. Controversies between these diverse theologies were sharp but in general did not cause any further basic divisions of the churches.

Social Tensions.—During the decade 1937-46, religion increasingly concerned itself with problems of the social and economic order. In repeated declarations beginning with the Oxford World conference of 1937, it was insisted that a righteous social order should recognize "the native

worth and dignity of man," that human labour should not be treated as a mere commodity, and that over-emphasis on the profit motive was wrong. The course of human history in the decade vividly high-lighted the issues at stake; the totalitarian powers, the challenge of the U.S.S.R., labour government in England and planned economy in the United States, heightened attention to the role of religion as an interpreter of these "secular" fields. The Roman Catholic position was elaborated in clearcut and highly important papal encyclicals which gave the Catholic Church a distinct moral advantage, while the actual absence from the white Protestant churches of the U.S. of the organized labour element, was a matter of active self-criticism and reproach. The increased number of Negro industrial workers went far towards evening the balance between the faiths at this point. Throughout the period authoritative Protestant pronouncements on social and economic matters inclined to be "leftish." Thus, the important Malvern conference in England, sponsored by Dr. William Temple, later archbishop of Canterbury, while defending private property, proposed its extensive limitation on moral grounds. In all this period it was hard to find an unconditional defense of the existing economic order by an influential Protestant church body. The churches were subject to increasingly aggressive cultivation both by the C.I.O., whose able representatives attended most important church conferences, and by the National Association of Manufacturers, which after 1940 maintained a committee for "conference with the churches."

Other Ethical Issues.—Two other major ethical issues were (1) imperialism as instanced in India, China and the colonial system in general, also in indirect controls by the United States in Central and South America; (2) racial injustice, primarily in Negro-white relations, including frequent segregation in the church itself, and especially when coupled with cultural and religious antagonisms as in the case of anti-Semitism. In deliberate contrast with ameliorative philanthropy and mere theological teaching in the pulpits and schools, "social action" departments were set up by numerous denominations, which directly participated in industrial controversies, and set up radical experiments in human relationships.

Church and State.—The totalitarian regimes uniformly undertook direct control of the churches within their territories and limited freedom of worship. The claims of the state to be supreme were interpreted by the churches as virtually the setting up of rival gods. State authoritarianism was stoutly resisted by elements of the German church, both Protestant and Catholic. The churches in the several occupied countries, notably Norway and Holland, became centres of stubborn resistance throughout the war. In Japan, the totalitarian government forced upon the relatively feeble church forms of emperor worship and complete state control. In the soviet union, the government first oppressed the church in behalf of official godlessness, but at the end of the decade was showing an inclination to use the church as a political pawn in the traditional Byzantine fashion. In the soviet sphere of influence there was a mass transfer of Uniate Catholics in Galicia to an Eastern Orthodox jurisdiction. The rising consciousness and more independent course of the Arab peoples in the near east intensified problems between Christianity and Mohammedanism. All nations coming to independence were naturally inclined to raise issues of nationalism versus foreign influences in the field of religion. Pandit Jawaharlal Nehru, however, reassured the Christian world with

respect to missions in India. The western churches exerted successful pressure toward bringing a declaration of personal freedom, including freedom of religion, into the charter of the United Nations, and pressure continued to get it implemented by specific requirements in the peace treaties.

The War Ordeal and Postwar Developments.—Representatives of the World Council of Churches, then in process of formation, were dispersed by the beginning of hostilities. Churches in nations which became immediately belligerent were compelled to make early choices between active participation in the war or obstruction of the war effort. Almost uniformly confessing wrong on both sides and minimizing hatred throughout the conflict, they invariably went along with their respective nations. Active criticism of war measures was, however, kept alive in all the democratic countries. The Methodist General conference in 1939 resolved that it could not support or participate in war; in 1941, the general assembly of the Presbyterian Church, U.S.A., barely defeated a proposal to repeal the historic doctrine of that church that a "just war" might be supported. As the war progressed, however, the churches reached the practically unanimous conclusion that it was their duty to support the nation in this crisis. From 1941 the pacifists ceased active opposition. Most of the drafted members of the historic peace churches declined to claim exemption as conscientious objectors. Justification for support of the war was found in such arguments as that relied upon by the *Christian Century*: that Christian conduct must be relative to time and place and that no absolutely good or bad alternatives are open in a war period. Besides the recruiting of the chaplaincy, extensive war services sprang up in all the churches and resulted in far-flung co-operative measures. Thus, the war emergency activities of the Federal Council of Churches doubled its normal expenditure.

Many churchmen, however, remained perplexed over the churches' seeming inconsistency both of thought and conduct.

The churches' postwar attitudes were expressed, on the one hand, in vast measures of relief and rehabilitation extending both to the oppressed peoples and almost immediately to the defeated belligerents; and on the other hand in concern for creating conditions for a just and durable peace. A series of representative U.S. study conferences authorized by the Federal Council of Churches made important contributions at this point, such as the modification of the Dumbarton Oaks proposals in a more definitely Christian direction and the support of the United Nations. No solid agreement, however, was reached as to immediate U.S. postwar policy.

In 1946 most of the church gatherings, both denominational and interchurch, were opposing peacetime conscription.

Interfaith Co-operation and Conflict.—Oppression at the hands of the totalitarian regimes tended to unite the separated Christian churches in sympathy and common resistance. Protestant and Catholic fronts in Germany reinforced one another. In 1941, Roman Catholic, Church of England and Free Church leaders of Great Britain joined in a significant wartime declaration, directly supplementing a Papal utterance, and parallel action by the united Protestant bodies and the Catholic Sword of the Spirit movement went forward along important lines. Practical

sympathy and some measure of protection were extended European Jews as among the chief victims of persecution, and the organization and utterances of interfaith movements in the U.S. sought to check anti-Semitism. Serious tensions, nevertheless, arose and were even accentuated in the postwar period.

(See, however, **CHRISTIAN UNITY**.)

No attempt could be ventured on the basis of this brief review to draw up a balance sheet for religion. The factors canvassed were of very unequal weight. On any mere listing, gains appeared much to exceed losses, and might ultimately prove to outweigh them in the scales of history as well as possibly in the judgments of eternity. (See also **CHURCH MEMBERSHIP**; **LIBERALISM**; **MISSIONS, FOREIGN**; **SUNDAY SCHOOLS**; also under separate denominations.)

Renner, Karl

Renner (1870-), Austrian statesman, was born Dec. 14, 1870, the son of a peasant, at Dolní-Dunajovice in Moravia (then part of Austria-Hungary). He joined the Social Democratic party in his youth and was elected to the Austrian parliament in 1907. A powerful influence among the Social Democrats, he became leader of that party and repeatedly attacked the government.

After the fall of the monarchy Renner became the first chancellor of the new Austrian republic. During the chaotic era that followed conclusion of World War I, Renner successfully steered the republic through political attacks from both right and left. He headed the Austrian peace delegation that signed the treaty of St. Germain-en-Laye on Sept. 10, 1919.

After a conflict with the Christian Socialists in his cabinet Renner lost the chancellorship in June 1920. He stayed in the cabinet as foreign minister for four months, resigning in October. Thereafter, his influence rapidly declined.

Toward the close of World War II it was announced in Moscow (April 29, 1945) that Renner had been named chancellor of an interim Austrian regime. His cabinet was made up of a coalition of Social Democrats, Christian Socialists and Communists. Renner proclaimed Austria's independence on May 14, 1945, abolishing all nazi laws and restoring the laws of the former republic; his government was recognized by the Allied Control Council for Austria on Oct. 20, 1945.

After the victory of the Catholic People's party at the polls, Nov. 26, 1945, Renner resigned as chancellor, but the following month (Dec. 20), he was elected president of

the second Austrian republic by unanimous vote of parliament.

Reparations (World War II)

While Allied guns were still shelling Cologne and the Rhine remained a barrier to penetration of Hitler's reich, the U.S.S.R. brought up the question of World War II reparations at the three-power conference held at Yalta, Feb. 4-11, 1945. Among other things, the U.S.S.R. proposed that German reparations be set at approximately \$20,000,000,000, of which it would get half. Although the United States agreed to consider this proposal as a basis for discussion, it made no commitment on the soviet proposals; neither did Great Britain.

The Yalta conferees agreed that Germany, after its defeat, should be made to compensate the Allies for damages sustained as a result of the German aggression, such compensations to be made "in kind" to the greatest extent possible, including use of German labour. They also agreed to establish a reparations commission at Moscow.

The Allied Commission on Réparations met at Moscow, June 11-July 14, 1945. It comprised: for the United States, Edwin W. Pauley, personal representative of the president; for the United Kingdom, Sir Walter Monckton; for the soviet union, Ivan M. Maisky, Deputy Commissar for Foreign Affairs.

The commission reached general agreement on a plan providing for (1) maximum possible compensation "in kind"—in goods as opposed to money—to the Allied nations on the basis of their contributions and losses in bringing about the defeat of Germany; (2) elimination of Germany's war-making power through removal of machinery and equipment not essential to a minimum German civilian economy; and (3) maintenance of sufficient German means of livelihood to obviate the necessity of Allied support of the German people.

The commission's plan was approved by the Big Three conference at Potsdam, July 17-Aug. 2, attended by the heads of the United States, the United Kingdom and the U.S.S.R. and their foreign secretaries. The conference, however, placed reparations on a zonal basis, under which the U.S.S.R. would obtain its reparations from the soviet zone of occupation, plus certain German external assets. In addition the soviets would receive outright 10% of the industrial equipment removed from the western zones, plus an additional 15% from the western zones for which they would pay in an equivalent value of food, coal and other products. It was provided that Poland's claims for reparations would be met from the soviet union's share.

The claims of all other countries would be met, under the Potsdam agreement, from the zones occupied by the United States, the United Kingdom and France, plus certain German external assets.

Power of decision on removals from Germany was vested in an Allied Control council (*q.v.*), composed of the heads of the military governments of the four zones. Under the Potsdam protocol, reparations removals were to be completed two years after the amount and character of German industrial equipment unnecessary for the German economy had been determined by the council.

From Nov. 9 to Dec. 21, 1945, representatives of 18 nations held the Paris Conference on Reparations. The conference agreed on the percentage share each nation was entitled to claim of total reparations from the western zones of occupied Germany. The conference established the Inter-Allied Reparations agency, composed of a representative of each nation, to allocate German reparations among the signatory nations.

Meanwhile, during the Potsdam conference, the heads of the governments of the United States, the United Kingdom and China had issued a proclamation offering terms of surrender to Japan, which included a provision that Japan would be allowed to maintain such industries as might sustain its economy and pay reparations, but not re-arm for war.

Three months after V-J day a U.S. reparations mission headed by Ambassador Pauley arrived in Tokyo to determine how much of Japan's industrial plants and industrial equipment should be removed as reparations. A report of this study together with recommendations for immediate removals of certain Japanese industrial equipment was submitted to the President Dec. 18, 1945.

Within six months the Far Eastern commission, comprising representatives of 11 nations which had warred against Japan, adopted policies defining interim removals of Japanese industrial installations, largely based on the Pauley report.

In May 1946, Ambassador Pauley, at the request of the president and secretary of state, returned to the far east with a mission of experts to study industrial installations of Korea and Manchuria and the needs of those countries in relation to reparations removals from Japan. The principal purpose of the mission was to obtain information and make recommendations to assist the United States and its Allies in planning a program of economic rehabilitation for the far east designed to contribute to the peace and security of that area and of the world. Following the mission to the far east, Ambassador Pauley went to Europe

Republican Party

The Republican party made a slow, uphill climb through the decade 1937-46, and in the difficult ascent it found itself forced to discard its 1920-40 attitude on many major questions of domestic and foreign import. When the G.O.P. returned to power on Capitol hill in the congressional election of 1946 after the longest exile in its 90 years of existence, it had shifted from its earlier policy of nonintervention to one of limited co-operation in world affairs. It had also embraced many social and economic reforms which it had abhorred when they were first proposed by Franklin D. Roosevelt.

It still remained, however, the party of conservatism and of trust in the system of private enterprise. It made its concessions to new national and world demands slowly and cautiously in accord with its traditions.

The Republicans' disastrous defeat in 1936 was partially responsible for this metamorphosis. Alfred E. Landon carried only Maine and Vermont and the party suffered accordingly. It elected only 17 senators, 89 house members and 8 governors.

Through 1937 and 1938 the party remained in an apathetic state. John D. M. Hamilton, who had been named national chairman by Landon, had to devote most of his time to liquidating the heavy debt incurred in the 1936 struggle. The Republicans in congress were too few to function as a parliamentary opposition.

Downslide Arrested.—It was not until Nov. 8, 1938, that the Republicans reversed an eight-year downward trend. On that election day they elected 8 new senators, 81 additional members of the house and boosted their total of governors to 18. Although their principal victories were scored in the agricultural midwest, they made substantial gains in New England and the industrial east.

Two young but important figures made their bow on the Republican stage in the 1938 contest. Thomas E. Dewey, brilliant New York lawyer, lost the gubernatorial race to Herbert H. Lehman by a narrow margin. In Minnesota, 31-year-old Harold E. Stassen defeated Elmer A. Benson for the governorship, ending Farmer-Labor control. In Wisconsin, the La Follette machine was badly damaged when Philip La Follette was defeated for reelection as governor.

The party began to play a more active part in national affairs in 1939. Its increased membership in congress—23 senators and 169 house members—enabled it to provide real opposition, especially in alliance with rebellious, conservative Democrats.

Senator William E. Borah of Idaho, who led the nonintervention bloc within U.S. Republican party ranks in 1939 after the outbreak of war in Europe. Sen. Borah died in 1940 before the U.S. entry into World War II

Even before the outbreak of World War II, the G.O.P. took a strong stand against U.S. involvement in European power politics. Its chief spokesman on foreign matters, Sen. William E. Borah of Idaho, bluntly told Pres. Roosevelt at a White House conference: "My sources of information are as reliable as yours. There will be no war in Europe!" With a few exceptions, the minority opposed the administration's attempt to repeal the embargo on shipment of arms to belligerents, even after Adolf Hitler's attack on Poland.

The spectacular struggle for the presidential nomination in 1940 helped to bring the Republicans to life—and hope. They needed drama to arouse public interest and imagination, and they got it. Moreover, it appeared that they might have an outside chance to win, because it had become evident that Roosevelt meant to try to break the two-term tradition. Until he broke it twice, it was thought that the U.S. people might rebel against such a violation. Three men appeared to share the lead in early 1940. They were Dewey, Sen. Arthur H. Vandenberg of Michigan and Sen. Robert A. Taft of Ohio. When Dewey defeated Sen. Vandenberg in the Wisconsin and Nebraska primaries, the contest seemed to narrow down to the New Yorker and the son of the former president.

But when these two contenders deadlocked on the early ballots, the convention turned to Wendell L. Willkie, utility lawyer and magnate, on the sixth roll call. He had captured the public fancy by a whirlwind, last-minute campaign, although this was his first adventure in politics. Sen. Charles L. McNary of Oregon was named for the vice-presidency. Willkie selected Rep. Joseph W. Martin, Jr., of Massachusetts, house minority leader, as his national chairman.

Opposing participation in foreign wars, the platform urged a stronger national defense, demanded a cut in federal expenditures and denounced the grant of "excessive power" to the president by the Democratic congress. Willkie, however, endorsed many New Deal reforms and projects, merely maintaining that he could execute and manage them more efficiently and economically.

In the Nov. 5 elections, Willkie polled 22,304,755 votes against 27,243,466 for Roosevelt. It was the largest popular vote ever given to a Republican presidential nominee. The electoral tally was 449 to 82. Willkie carried ten states: Maine, Vermont, Michigan, Indiana, Kansas, Nebraska, Iowa, North Dakota, South Dakota and Colorado. The G.O.P. gained 5 senate places for a total of 28. It lost 7 in the house, reducing its membership to 162. It raised its gubernatorial quota from 18 to 20.

After his defeat, Willkie threw himself into the crusading

role that was to give him great influence in shaping Republican thought on the European conflict and world affairs. Returning from a trip to England, he urged all-out aid to Great Britain. He testified before congressional committees in favour of enactment of the pending lend-lease bill, boldly admitting that his earlier pledges to keep the U.S. out of war, if elected, had been only "campaign oratory."

For a while, however, G.O.P. sentiment on Capitol hill remained predominantly non-interventionist. A majority voted against the administration proposal to amend the Neutrality act to permit the arming of U.S. vessels. Only 23 house Republicans supported lend-lease. Only 7 senators and 21 in the house voted for extension of the draft act, which squeezed through the lower body by only one vote.

With the Japanese attack on Pearl Harbor on Dec. 7, 1941, the Republicans joined the Democrats in mobilizing the nation's resources for war against the axis. Only one member, Jeannette Rankin, Montana Republican, opposed the declaration of hostilities against Japan on Dec. 8. Both houses unanimously approved the war challenge to Germany and Italy on Dec. 11. On Dec. 10, in an exchange of letters, Rep. Martin and Edward F. Flynn, Democratic national chairman, agreed to abandon partisanship on all questions affecting prosecution of the struggle.

Toward Internationalism.—The G.O.P. moved nearer Willkie's international platform when the national committee met at Chicago in April 1942, to redefine its position on war issues. The 1940 standard-bearer urged a statement favouring U.S. co-operation in building a new world order. Senator Taft held that there should be no declaration on postwar policies until after the close of the conflict. The foreign policy resolution finally adopted said: "We realize that after this war the responsibility of the nation will not be circumscribed within the territorial limits of the United States, that our nation has an obligation to assist in the bringing about of understanding, comity and co-operation among the nations of the world in order that our own liberty may be preserved and that the blighting and destructive processes of war may not again be forced upon us and upon the free and peace-loving peoples of the earth."

In a "declaration of policy," house Republicans subsequently endorsed this acceptance of the fact that the U.S. should face and meet international responsibilities after the war.

The 1942 congressional contests restored the Republicans to the status of an effective opposition on Capitol hill. They gained 10 additional senate seats, giving them 38. In the house they increased their strength to 209, or 9 less than a nominal majority. They added 5 governorships to their list for a total of 23, including New York, California and Michigan.

Two of the more prominent figures who came to power at this time were Dewey, who was elected governor of New York, and Earl Warren, who was elected governor of California. John W. Bricker was re-elected governor of Ohio and Stassen won similar honours in Minnesota.

G.O.P. congressional gains in 1942 meant the death of New Deal domestic reforms. In alliance with about 60 southern Democrats in the house and 15 in the senate, the Republicans were usually able to defeat or sidetrack any measure they opposed.

Following the November election of 1942, Rep. Martin submitted his resignation as national chairman. He was succeeded by Harrison E. Spangler, Iowa lawyer,

farmer and business man, who gave full time to the post and set out to build up an organization from the grass roots.

Casting aside the last vestige of non-intervention, the G.O.P. in 1943 subscribed to a program of full United States association with other democracies and peace-loving nations in the postwar era. Meeting at Mackinac Island, Mich., on Sept. 7, 1943, in what amounted to an off-year convention, the Postwar Advisory council declared for "responsible participation by the United States in postwar co-operative organization among sovereign nations to prevent military aggression and to attain permanent peace with organized justice in a free world."

The G.O.P. formally underwrote this pledge when the minority representation in congress voted overwhelmingly for the Fulbright resolution in the house and the Connally resolution in the senate. These two proposals committed the U.S. to support of an international organization "with adequate power" to preserve world peace—a program that led to creation of the United Nations.

The Mackinac convention, however, condemned the administration's domestic policies. After advocating greater encouragement of "private enterprise" and postwar "termination of rationing, price-fixing and all other emergency powers," the council said:

"The present program of the New Deal Administration, with the enlargement thereof set forth in the reports of the National Resources Planning Board, would wreck the country because the only remedy it proposes is unlimited government spending of borrowed money. It would sacrifice business, agriculture and the professions. It would extend the power of government until ultimately no man or woman could act, write or speak without approval. It would substitute for American liberty the regimented existence of a subject people."

National Chairman Spangler reported that he had placed Washington headquarters on an all-year-round basis, with a staff of full-time publicists and researchers, whereas previously it had been dark and inactive save for a few weeks before each election. When Rep. J. William Ditter of Pennsylvania was killed in an aeroplane accident in late November of 1943, he was succeeded as chairman of the Republican congressional committee by Rep. Charles A. Halleck of Indiana.

The political wisdom of the foreign policy shift at the Mackinac Island meeting became evident from the results of early 1944 primaries. Such arch-opponents of intervention as Rep. Hamilton Fish of New York, Stephen A. Day, Illinois congressman-at-large, and Melvin J. Maas of Minnesota were retired by Republican constituents who had hitherto shown a prejudice against U.S. involvement in world affairs.

The Republican national convention took note of this changing sentiment when it assembled at Chicago in June. After a short session in which three governors were the principal contenders—Dewey of New York, Bricker of Ohio and Warren of California—the delegates nominated Dewey for president and Bricker for vice-president on a platform that incorporated the Mackinac statement and specifically pledged "collaboration" with the United Nations, which had already begun to assume shape at a meeting of world statesmen at Dumbarton Oaks, Washington, D.C. In fact, John Foster Dulles, Dewey's adviser on foreign affairs, acted as Sec. Cordell Hull's aide at these preliminary U.N. sessions.

The G.O.P. also made many concessions to New Deal

domestic reforms, as did Dewey in his campaign utterances. The platform "accepted the purpose" of the National Labor Relations act, the Wage-Hour act, the Social Security act and "all other statutes designed to promote and protect the welfare of the American workingmen and women." Indeed, it recommended extension of old-age and unemployment insurance to employees not already covered.

To the farmers, in language paralleling Democratic promises, the Republicans offered "an American market price . . . and the protection of such price by means of support prices, commodity loans or a combination thereof."

But the platform, and later Gov. Dewey, sharply condemned the Democratic administration of these reforms. The Republican candidate reiterated that the federal government was managed by "tired, quarrelsome old men" and insisted that "it is time for a change."

"Don't Change Horses."—Although Dewey's sharp and forceful campaigning forced Roosevelt to forego his original plan of not seeking votes "in the conventional sense," the New York executive led a hopeless cause. Voters hesitated to change a commander in chief in mid-conflict. U.S. troops under Dwight Eisenhower and Douglas MacArthur, respectively, had landed in Normandy and on the outer Philippine Islands. Organized labour, especially Sidney Hillman's C.I.O. Political Action committee, rang doorbells and registered Roosevelt voters in all the great industrial centres. In the last few weeks of the battle, Roosevelt delivered six of his most stirring appeals, winding up with the promise to provide 60,000,000 jobs in the postwar period.

The popular vote was 25,602,505 for Roosevelt and 22,006,278 for Dewey. The electoral count was 432 to 99. The Republican nominee carried 12 states: Maine, Vermont, Ohio, Wisconsin, Indiana, Kansas, Nebraska, Iowa, Colorado, North Dakota, South Dakota and Wyoming. The Republicans made a net gain of 1 senate seat for a total of 38, a figure soon to be increased to 39 through the death of Frank Maloney, Connecticut Democrat, and the appointment of Thomas C. Hart, Republican, to the vacancy.

The G.O.P., oddly enough, lost 19 house places, giving them 190 seats as against 243 for the Democrats. There was one representative of the American Labor party and one Farmer-Laborite.

The Republicans used the off-year of 1945 to strengthen their national organization and to formulate definite principles on which to try to regain control of congress in 1946 and of the White House in 1948. Meeting at Indianapolis on Jan. 22, 1945, the national committee approved National Chairman Herbert E. Brownell, Jr.'s program of headquarters' expansion. He immediately established new departments for handling problems involving radio, research, labour, veterans, women, young Republicans, finances and speakers. John A. Danaher, former senator from Connecticut, was named legal counsel and congressional liaison man. William C. Murphy, Jr., veteran Washington correspondent, was placed in charge of publicity. Hugh R. Wilson, former ambassador to Germany and assistant secretary of state, was selected as adviser on foreign affairs.

A congressional policy committee, headed by Sen. Taft of Ohio and Rep. Halleck of Indiana, framed a statement of aims and principles for party field workers and candidates. Although it received a mixed reception as "too vague" and "too conservative," it was endorsed by the

national committee at a Chicago meeting on Dec. 8, 1945.

"Today's major domestic issue," said the document in part, "is between radicalism, regimentation, all-powerful bureaucracy, class exploitation, deficit spending and machine politics, as against our belief in American freedom for the individual under just laws fairly administered for all, preservation of local home rule, efficiency and pay-as-you-go economy in government, and the protection of the American way of life against either fascist or communist trends. . . ."

"In foreign affairs we shall continue to strive to avoid partisanship. But we shall also seek to avoid secrecy, inefficiency and drift. . . . We consider that the maintenance of a strong, solvent and free America is the basis of our greatest contribution to world order."

Several key G.O.P.-ers translated into action the pledge to "avoid partisanship" in foreign affairs. By appointment of Pres. Roosevelt, Sen. Vandenberg and ex-Gov. Stassen were members of the U.S. delegation to the April 1945 San Francisco convention which chartered and organized the United Nations. Vandenberg subsequently served as adviser to Secy. James F. Byrnes at many U.N. conferences in the U.S. and in Europe. Ex-Sen. Warren R. Austin of Vermont was an important member of the U.S. delegation to the conference of Chapultepec, which framed plans for a Pan-American alliance. President Harry S. Truman later named him as the nation's representative to the U.N.

The Republicans in congress rallied behind Harry S. Truman when he entered the White House upon Roosevelt's death on April 12, 1945, but the nonpolitical honeymoon was short-lived. The end of the war against Japan on Aug. 14, 1945, stirred twinges of partisanship, but it was the new executive's legislative program, which he submitted to congress on Sept. 6, 1945, that terminated the Pennsylvania avenue alliance. G.O.P. leaders branded it as "ultra-New Dealish," whereas they had expected more moderate and temperate demands, and immediately joined with conservative Democrats to modify or defeat the presidential proposals.

Less than 50% of Truman's requests became law and many of those only in a drastically amended and diluted form. For example, his demand that congress establish economic machinery for providing "full employment" emerged from the legislative mill only as a pious and generalized admission that it would be beneficial to the individual and the country if every able-bodied man and woman could have a job.

Truman's legislative relationship with the second session of the 79th congress had a far-reaching political effect. His inability to obtain favourable action on labour, racial, social and economic measures from an overwhelmingly Democratic congress antagonized those elements which would have benefited from their passage—elements, too, which had always voted enthusiastically for Roosevelt. His helplessness in the face of a bipartisan coalition on Capitol hill aroused popular suspicion that he lacked force and decisiveness.

Momentum.—The 1945 elections were sporadic and confined to local battlefields. But they showed trends favourable to the G.O.P., based on the loss of so striking a leader as Roosevelt, a defection from the less magnetic Truman, a breakup of the heterogeneous Democratic (New Deal) organization and the first clash between a Democratic ad-

Floodlights playing down on more than one thousand delegates assembled at the Chicago stadium for the Republican national convention in 1944

Demonstration for Governor Thomas E. Dewey of New York at the Republican National convention in Chicago before he was nominated as the party's presidential candidate on June 28, 1944.

ministration and important groups of organized labour in 12 years.

The G.O.P. carried all three special elections held after Truman became president—in New Jersey, Illinois and Montana. National Chairman Brownell said he thought the results significant because the Democratic candidates in New Jersey and Montana had campaigned on a "Support Truman" platform.

The Republicans also scored important mayoralty victories in such industrial and democratic centres as Detroit, Buffalo, N.Y. and Hartford and New Haven, Conn. In the automobile capital, Mayor Edward J. Jeffries was re-elected over Richard T. Frankensteen, vice-president of the United Automobile Workers of America, a C.I.O. union. Although Detroit had a nonpartisan election system, Democratic National Chairman Robert Hannegan backed Frankensteen. Labour disturbances in the area were held partially responsible for the defeat of the C.I.O. entry.

William F. O'Dwyer, the Democratic nominee, won the New York city mayoralty contest after 12 years of Tammany exile under F. H. La Guardia, who did not seek re-election. However, of 2,000,000 votes cast, O'Dwyer got merely 840,000 under the party emblem or only a few thousand more than the combined total polled by his opponents. He owed his great lead to the support of the American Labor party and liberal ballots. Newbold Morris, whom Mayor La Guardia backed in protest against both the Democratic and Republican nominees, rolled up the surprising total of 399,437 votes without benefit of money or organization.

With the Republicans leading the attack, the anti-Truman coalition on Capitol hill delivered a heavy and incessant barrage against the administration during the second session of the 79th congress, which convened in Jan. 1946. The Democrats' weak points were deliberately selected in the parliamentary battle.

In framing a measure for extension of OPA, Sen. Taft and Sen. Kenneth Wherry of Nebraska, minority whip, forced adoption of amendments allowing greater profits

to producers and processors. Although his congressional aides urged him to sign the bill, President Truman vetoed it on the ground that "it would wreck OPA and cause inflation." His veto was upheld by a narrow margin.

Congress re-enacted a slightly modified measure, and the chief executive accepted it, albeit reluctantly. This statute provided for a "meat holiday" from OPA controls for two months—July and August—but it permitted administration agencies to reinstate price ceilings if production did not meet demand. It was generally believed that this provision proved politically damaging to the Democrats.

During the few weeks of decontrol, meat began to come into local markets. With the reimposition of controls on Sept. 1, however, a severe meat famine struck the nation's tables. Truman's own leaders begged him to remove meat ceilings, and the president reluctantly complied on Oct. 14. When supplies of beef, pork and lamb became more plentiful only a few days before the Nov. 5 election, the people apparently concluded that the administration's earlier insistence on retention of federal regulation had been a major miscalculation and blunder.

Angered by a series of strikes that increased prices and handicapped production, congress passed the Case bill, which imposed drastic curbs and responsibilities on labour. Pres. Truman vetoed the bill, proposing a general study of the labour problem instead and his veto was sustained by only five votes in the house. His alternative suggestion was not even considered, nor was his proposal for authority to induct into the armed forces any worker who struck against a key industry after it had been taken over by the government.

Truman's labour policy appeared to make enemies for the administration on all sides. Conservatives criticized him for his veto of the Case bill. Labour spokesmen, including C.I.O. President Philip Murray, branded him as an "enemy" because of his "draft" counter-proposal.

The G.O.P. also tried to capitalize on the charge that

the Democrats tolerated "communist" allies for vote-getting purposes. In senate and house, opposition leaders reiterated demands that "reds" and "pinks" be discharged from the federal pay roll. The Wallace episode (see DEMOCRATIC PARTY) as well as Moscow's recalcitrant behaviour at postwar peace conferences, operated to the disadvantage of the Democrats.

Republican National Chairman B. Carroll Reece summed up the campaign from his viewpoint with the comment that, "The outstanding issues are the three C's—communism, confusion and controls." Originating in Boston, the G.O.P.'s most punchy and appealing battle cry was: "Had enough? Vote Republican!" It swept the nation on waves of laughter.

It was a curious campaign. Whereas Democratic candidates for national office based their appeal on strictly local issues, Republican nominees for the most unimportant local positions relied on national issues and shortcomings for victory. The "ins" avoided any discussion of the administration at Washington, while their opponents talked the "three C's" almost exclusively.

Victory.—On Nov. 5, 1946, the accumulated grievances of 13 years, the war and postwar irritations and discord between the left and right wings of the Democratic party combined to produce a Republican landslide from coast to coast. It was one of the worst defeats that a major party had suffered in a mid-term test.

The Republicans regained absolute control of congress by substantial margins. They increased their senate membership from 39 to 51. They took back senate seats in such important and scattered states as Massachusetts, New York, Pennsylvania, Delaware, Ohio, Missouri, Wisconsin, Minnesota, Montana, Utah and Washington. They lost senatorial races by majorities of 2,000, 3,000 and 5,000 respectively, in Maryland, West Virginia and Wyoming.

The Republicans raised their representation in the house from 192 to 246. The Democrats retained 188 places, and the American Labor party had one—Vito Marcantonio of New York city. In addition to winning back the legislative branch, the G.O.P. increased the number of governorships held by their party to 25, or all but 7 outside the south and the border states. The opposition outvoted the Democrats in the congressional contests by 3,000,000. Most significantly, the Republicans carried great cities which had been swept by the Democrats since Roosevelt's appearance on the political scene.

Temporarily at least, the G.O.P. seemed to have won back numerous elements of the electorate which had been off the old reservation for many years, such as Negroes, populous racial groups, the small business men and white-collarites and also a large segment of the so-called workingman's vote.

The 1948 presidential spotlight immediately shifted in the direction of several prominent figures who won their respective contests by tremendous majorities, ranging from 400,000 to 700,000. They were Gov. Dewey of New York and Gov. Warren of California, who were re-elected. Others were Gov. Edward Martin of Pennsylvania and ex-Gov. Bricker of Ohio, who were advanced to the senate.

Two incumbent members of the senate also figured in 1948 speculation. The first was Sen. Vandenberg, who won re-election easily without even returning to Michigan; his role as foreign policy spokesman proved a great asset. The other was Sen. Taft, who had long held the leadership of the more conservative forces in the upper chamber.

When fear was expressed in the United States and elsewhere that the Republican triumph might mean a radical change in U.S. foreign policy, Sen. Vandenberg assured the

United Nations assembly at New York that the program would not be disturbed. Assembling at Washington immediately after the election, the Republican steering committees of house and senate promised a maximum of co-operation with Pres. Truman on domestic questions.

Despite some members' complaint that a few veterans were "monopolizing" the leadership posts, senate Republicans of the 80th congress put through their prearranged slate, as follows: president pro tem, Sen. Arthur H. Vandenberg of Michigan; majority leader, Sen. Wallace H. White, Jr. of Maine; chairman of the steering and policy committee, Sen. Robert A. Taft of Ohio; chairman of the conference committee, Sen. Eugene D. Millikin of Colorado.

Former minority leader Joseph W. Martin Jr. of Massachusetts was elected speaker of the house by unanimous vote. Rep. Charles A. Halleck of Indiana was selected as majority leader. (See also ELECTIONS; UNITED STATES.)

Reuther, Walter Philip

Reuther (1907–). U.S. labour leader, was born Sept. 1, in Wheeling, W.Va. The son of a trade unionist, he studied at Wayne university (Detroit) for three years and then, with his brother, Victor, toured (1933-35) France, Germany, Italy, the soviet union, China and Japan to study labour conditions. On his return to the U.S., he worked in small tool and die shops and organized and became president of the United Automobile Workers Local 174, which embraced employees of a number of small plants.

Reuther organized the successful sitdown strikes in the Detroit automobile and related industries (1936-37) and was named one of the union's two vice presidents (1942). After keeping work stoppages at the General Motors plants to a minimum during World War II, he launched a post-war campaign to obtain higher wage levels. He demanded (Sept. 14, 1945) a 30% increase for U.A.W. workers in G.M. plants, contending that the corporation could grant this increase, reduce motor car prices substantially and still make large profits. The corporation's rejection of these demands resulted in a strike starting Nov. 21, in

which upwards of 180,000 U.A.W. union members in G.M. plants throughout the country quit work. Reuther's proposals that G.M. open its books to determine the company's ability to pay the 30% increase were rejected by the corporation which said Dec. 20, that compliance would lead to "the death of the American system of competitive enterprise." The strike continued for 113 days before it was settled March 13, 1946, after Reuther agreed to an 18½ cent hourly pay increase and adjustments in overtime and vacation pay.

After the strike, Reuther was elected president of the U.A.W., March 27, by a narrow margin over his predecessor, R. J. Thomas; but his victory was incomplete as nearly two-thirds of the seats on the union's international executive board went to his political foes.

Reynaud, Paul

Reynaud (1878–), French statesman, was born Oct. 15, 1878, at Barcelonnette in the Basses-Alpes department. He received his doctorate of law from the University of Paris in 1904 and served throughout World War I, receiving the *croix de guerre*. Elected to the chamber of deputies from the Basses-Alpes in 1919, he held a number of important ministerial posts in conservative French governments from 1930 to 1940. One of the few "voices in the wilderness" who warned Frenchmen against placing reliance in the Munich pact or Hitler's assurances, he succeeded Daladier as premier on March 21, 1940. Seven weeks later (May 10), German armies started their surprise attack on the Low Countries. The successive defeats of the French armies caused near-panic and hysteria in the French government. Striving vainly to bolster morale, Reynaud on June 6 reshuffled his cabinet. But the government evacuated Paris, June 10, moving to Tours and then to Bordeaux, June 14.

Reynaud resigned June 16 and was succeeded by Marshal Henri Pétain. After the armistice, Reynaud, along with other officials of the fallen Third Republic, was imprisoned by the Vichy government. In Nov. 1942, he was transferred to a German prison. Liberated in May 1945, by Allied troops, he returned to Paris and appeared as a prosecution witness in the trial of Pétain. Taking the stand, July 23, 1945, Reynaud asserted that he had been determined to carry on the war from Africa, but that he was afraid to buck Pétain, who opposed the plan. Reynaud was elected to the new constituent assembly June 2, 1946, and to the national assembly on Nov. 10, 1946.

Rhineland

Together with the neighbouring province of Westphalia, the Rhineland forms the most important industrial section of Germany and the indispensable economic basis of German military power. Its population in 1933 was 8,453,063 (area, 9,462 sq.mi.). Some of the largest cities in

the Rhineland are: Cologne (768,426 in 1939), Essen (659,871), Duesseldorf (539,905), Dortmund (537,000), Duisburg (431,256), Wuppertal (398,099), Gelsenkirchen (313,003), Bochum (303,288).

The chief part of the Westphalian basin and the hub of the German iron and steel industry is the valley of the Ruhr, a right bank tributary of the Rhine.

The Rhineland and Westphalia became part of Prussia in 1815. After World War I, to ensure fulfilment of the peace treaty, Allied troops occupied the left bank and the bridgeheads of the Rhine. In addition, to safeguard French security, the German territory west of the Rhine was to be permanently demilitarized. The occupied territory was to be evacuated in three stages in accordance with the fulfilment of the treaty; the right of reoccupation was reserved in the event of default. Originally the occupation was supposed to end in 1935; in reality the third and final zone of occupation was evacuated on June 30, 1930. German default in reparation payments led to a brief occupation by the French and Belgians of the Ruhr in 1923. In the treaty of Locarno in 1925 the Germans promised to respect the demilitarization of the Rhineland. Though Chancellor Hitler repeatedly stressed his adherence to the Locarno treaty, he broke his pledge in March 1936 and began to remilitarize and fortify the Rhineland. In World War II the Rhineland and Westphalia were heavily bombed. In 1945 the territory fell mostly into the British zone of occupation.

To avoid the renewed danger of German aggression the French government in 1945 insisted repeatedly to the other three occupying powers that a special regime for the Rhineland and Westphalia should be created. By such a regime not only was the security and peace of western Europe to be assured but also the industrial resources of the territory could become important factors in the economic reconstruction and integration of western Europe. The French considered definite arrangements for the western borders of Germany the more urgent because the eastern borders of Germany had been settled at the Potsdam conference.

Rhode Island

A north Atlantic state of the United States, in New England, Rhode Island is one of the 13 original states, popularly known as "Little Rhody." Area, 1,214 sq.mi. (smallest in the United States). Population (1940) 713,346, of whom 653,383 (91.6%) were urban. On July 1, 1944, the bureau of census estimated the population of the state at 778,972. Capital, Providence (253,504). Other cities: Pawtucket (75,797); Woonsocket (49,303); Cranston (47,085); Newport (30,532); Warwick (28,757); Central Falls (25,248).

At the regular 1937 session of the legislature, the gasoline tax was increased from two to three cents per gallon. A special commission was created to study the tax structure of the state. Acts provided strict regulation of child marriages, created a commission to study juvenile court procedure, ordered children between the ages of 7 and 16 to attend school regularly, and regulated traffic in alcoholic beverages. The most important political event of 1937 was the contest between Governor Robert E. Quinn and Walter O'Hara, manager of the Narragansett race track.

The climax was reached in the governor's proclamation of martial law effective in the vicinity of the track and his order closing the track for the latter part of the racing season.

At the 1938 session of the legislature, leading acts passed were annual appropriation bills totalling \$15,997,413; authority for holding special election for sanction of federal public works loans; an act relating to the holding of caucuses and elections; an act requiring blood tests before marriage; authority to Pawtucket to construct sewage disposal facilities; adding Jamestown ferry to the state highway system; an act to regulate practices of professional engineering; prohibition of use of tear gas during labour strikes or lockouts; an act to provide aid to the blind. State officers elected in Nov. 1938 were: William H. Vanderbilt, governor; James O. McManus, lieutenant governor; J. Hector Paquin, secretary of state; Louis V. Jackvony, attorney general; Thomas P. Hazard, general treasurer.

Important measures passed at the regular 1939 session of the legislature included an act reorganizing state departments by revising the reorganization act of 1935; an act creating a civil service system and a resolution proposing a civil service amendment to the constitution; an act allowing the mayor of Providence greater appointive power and providing for a charter commission to draft a charter revision for Providence; an act appropriating funds for investigation of voting frauds; acts creating commissions to study juvenile and district court legislation, election and caucus laws, direct primary and corrupt practices acts, labour legislation, division of Providence into five senatorial districts; an annual appropriation bill reducing state expenditures by more than \$1,000,000; acts levying a tax on cigarettes and all other tobacco products, increasing inheritance tax and rates for taxes on electric and communication utilities; an act exempting idle industrial properties from local taxation; an act creating a board of trustees for state colleges; an act ceding land to the federal government for a naval air base; and a resolution proposing a constitutional amendment banning dual office-holding.

Elected at the Nov. 1940 elections to the chief executive offices for 1941-42 were: J. Howard McGrath, governor; Louis W. Cappelli, lieutenant governor; Armand H. Cote, secretary of state; John H. Nolan, attorney general; Russell H. Handy, general treasurer. In the 1940 presidential elections Roosevelt received 181,122 votes; Willkie 138,214; Browder 239; Babson 74.

At the regular 1940 session of the legislature, measures were passed giving Providence a fifth seat and Pawtucket a second seat in the state senate; granting Providence a new charter; providing for a referendum on a nonpartisan system of municipal elections in Providence; modifying the requirement for mandatory certification of cases to the supreme court from lower courts on constitutional questions; establishing uniform aeronautics laws; making appropriations for support of the state totalling \$15,180,983 for the fiscal year 1940-41; appropriating \$50,000 for the use of the attorney general's department in investigating election frauds; allowing Providence to issue \$1,000,000 in funding bonds and \$750,000 in bonds for school improvements; requiring cities and towns asking authority from the legislature to issue bonds to provide specific information on their financial condition.

Measures passed during the 1941 session of the legislature included the following: amendments to the civil service law, giving the governor power to replace the commission; an act creating a four-member bipartisan board of elections; an act giving housing authorities the right to exercise the power of eminent domain; an act creating a

council of defense and authorizing local and district councils; an act guaranteeing to persons entering the armed forces a maximum unemployment compensation of \$16 weekly upon their discharge, as long as they were unemployed or as long as their wage credits lasted; amendments to the workmen's compensation law, increasing allowances for medical care and changing the base for computing compensation; an act extending the emergency period for state unemployment relief for one year and providing penalties for accepting relief fraudulently; an act creating a state labour relations board; and a new law of arrest.

The chief executive officers of the state elected in 1940 were re-elected in Nov. 1942 for 1943-44 terms. In the 1942 gubernatorial election McGrath (Dem.) received 139,407 votes and his Republican opponent, McManus received 98,741. Edmund W. Flynn was chief justice of the supreme court.

At the 1942 legislative session, measures were passed providing for absentee registration for service men; permitting citizens in the armed forces to vote by absentee ballot; granting leave of absence to state employees entering the armed forces or loaned to federal agencies; authorizing housing authorities to convert slum clearance projects to defense housing projects; giving general authorization to cities and towns to appropriate for civilian defense needs; granting emergency defense powers for the governor and state council of defense; placing the state sickness insurance system under the unemployment compensation board; providing for an increase of about 12½% in unemployment compensation benefits; providing for reduction of employee contributions to the unemployment compensation fund from 1½% to ½% of the individual's wages, the 1% being diverted to the new state sickness insurance fund.

In 1943 the legislature enacted measures extending the governor's emergency war powers for a year; exempting residents of the state from payment of interest on delinquent property taxes while in military service; providing penalties for an employer who refused to restore a job to a member of the armed forces if the member applied within 40 days of discharge and the employer was in a position to rehire him; appropriating \$20,000 to establish canning centres to tie in with the food conservation program; creating a commission to study the matter of bonuses for service personnel; authorizing state prisoners to participate in war production; regulating hours and conditions of employment of women and minors; creating a second injury indemnity fund; setting up a curative centre for injured workmen; making appropriations of \$17,759,970 for the support of the state for the fiscal year ending June 30, 1944; increasing from 3% to 4% the excise tax on financial institutions; placing a tax ceiling of 27.5 cents on each \$100 of deposits in credit unions; revising the unincorporated business tax; authorizing cities and towns to set up reserve funds to be spent on capital expenditures after the war; opening a specific area of the Sakonnet river to power dredging and providing for the opening of a comparable substitute area in Narragansett bay when the Sakonnet river became over-fished; providing for the conservation of soil and forest resources and the prevention and control of erosion.

Principal executive officers of the state elected in Nov. 1944 were J. Howard McGrath, governor; John O. Pastore, lieutenant governor; Armand H. Cote, secretary of state; John H. Nolan, attorney general; Russell H. Handy, general treasurer. In the presidential election, Roosevelt re-

ceived 175,356 votes; Dewey 123,487. No U.S. senatorial election was held. Edmund W. Flynn was chief justice of the supreme court.

The 1944 legislature enacted laws creating a separate juvenile court; authorizing a 1/2% increase in the tax on pari-mutuel betting; levying an additional tax on electric utilities; designating annual appropriations and special appropriations of \$50,000 for aid in planning postwar bridge and highway projects and \$58,450 for 19 charitable organizations; granting extension of the governor's emergency war powers for another year; permitting service personnel to vote on absentee ballots without registering; moving up the time for filing final nominations for federal

and state officers to July 10; recodifying the public assistance laws; creating a Rhode Island port authority; giving the public utilities administrator full control over intrastate commercial aviation; providing that absence in military service was not to affect continuity of employment; providing for a constitutional convention; providing for assistance to dependents of servicemen; authorizing the governor to offer to convey state property to the federal government for the erection of a veterans' hospital.

Governor McGrath resigned Oct. 6, 1945, to accept appointment as solicitor general of the United States and John O. Pastore became governor. Leading measures passed by the 1945 legislature included those giving seniority employment benefits to veterans of World War II; providing for establishment of veterans' retraining and re-employment committees and information service centres; providing for incorporation of nonprofit medical service corporations; providing for mandatory retirement of members of the state police force after 20 years; imposing an additional tax on the gross earnings of electrical corporations; granting annual appropriation of \$19,360,843 for support of the state government for the fiscal year beginning July 1, 1945; making available an additional \$1,000,000 for the relief of cities and towns in the state. Principal executive officers of the state elected in Nov. 1946 for 1947-48 were John O. Pastore, governor; John S. McLernan, lieutenant governor; Armand H. Cote, secretary of state; John H. Nolan, attorney general; Russell H. Handy, general treasurer. (M. C. ML.; X.)

Rhodesia, Northern

Northern Rhodesia is a protectorate of the British crown. It extends from Southern Rhodesia northward to the boundaries of the Belgian Congo and of Tanganyika territory; it is bounded on the east by Nyasaland protectorate and on the west by Angola. Area: 290,323 sq.mi.; pop. (est. 1940): 1,381,800 of whom 15,188 European and 1,366,600 African. Chief towns: Lusaka (cap., Europeans: 1,350); Luanshya (Europeans 1,800; Africans 22,000); Ndola (1,000; 8,000); Mufulira (1,100; 12,500). Languages: English, Chiwemba, Chinyanja, tribal dialects. Religion: Anglican, Catholic, nonconformist, Hebrew and pagan. Governor: Sir Enbule John Waddington (after May 31, 1941).

The main feature of the years 1937-46 in Northern Rhodesia was the economic development of the country as a whole, to which an immense impetus was given by the wartime demand for copper, deposits of which in the protectorate are among the largest in the world. From 1938-1943, 1,385,914 short tons of copper were produced for the Allies. In the same period were mined 3,482 short tons of lead, 72,243 short tons of zinc and 3,687 short tons of vanadium. In 1940 two mica mines were started. Some trouble was made by native employees on the mines in 1942. Apart from that, the mines remained in full production throughout World War II until 1946, when European artisans went on strike for more pay. The burden of transporting the mines' output to the coast put a heavy strain on the Rhodesian railways. These had, in addition, to contend with a strike of native employees in Jan. 1946 which spread from Southern Rhodesia. In Aug. 1946 plans

were announced for a new copper refinery which would enable much of the processing to be done within the territory. Many thousands of Africans served in the British armed forces during the war. (For statistical data, see under RHODESIA, SOUTHERN.)

(G. A. V.)

Rhodesia, Southern

A self-governing colony in South Africa, Southern Rhodesia extends from the Transvaal border northward to the boundaries of Northern Rhodesia; it is bounded on the east by Mozambique and on the west by Bechuanaland. Legislative power was vested in the king of England,

represented by a governor, while the executive power was vested in the governor, aided by an executive council. This council was chosen from a legislative assembly by the leader of the predominant political party, and ministers were appointed by the governor. The assembly was elected by popular vote. Africans qualified for enfranchisement in the same manner as Europeans. Area: 150,333 sq.mi.; pop. (1941 census): 1,448,393; (est. 1945): 1,576,310 of whom 81,470 European, 6,830 Asiatic and coloured, and the rest African. Chief towns: Salisbury (cap., 61,760); Bulawayo (39,817); Umtali (7,771); Gwelo (7,726). Languages: English, Afrikaans, various native languages. Religion: Anglican, Catholic, nonconformist, Hebrew, pagan. Governors: Sir Herbert J. Stanley (1934–1941); Sir Evelyn

*1942. †1943. ‡1937. §1941.

Baring (July 28, 1942–1944); Admiral Sir William Campbell Tait (Nov. 20, 1944–died July 1946); Major General Sir John Noble Kennedy (after Sept. 15, 1946). Prime minister: Sir Godfrey Martin Huggins (after Nov. 14, 1934).

The year 1937 was chiefly notable for the three-party agreement between the Union of South Africa, Southern Rhodesia and the Rhodesian railways binding the union not to exercise its option on the Vryburg Palapye railroad for 33 years. In March 1939 the report of the royal commission on the amalgamation of Southern and Northern Rhodesia, known as the Bledisloe report, was published; in April at the general elections the United party gained 23 of the 30 seats in the general assembly; the same month the natural resources report was published, while later in the year the Umshandige dam and the Otto Beit bridge at Chirundu were both opened. In 1940 the first empire air training school was opened; on Sept. 12, the colony celebrated its jubilee and Bulawayo town hall was completed; in October the association of chambers of industry was formed. In 1941 the colony formed a trade pact with Australia; De Beers ceded its diamond rights concession and a trade commission visited the Belgian Congo. All women between the ages of 16 and 54 were compulsorily registered for national service in 1942, in which year the first airgraphs were sent to England and gasoline rationing started; in August Southern Rhodesian forces came under command of the Union of South Africa. In 1943 standard flour was introduced; in April the Pole-Evans report on pasture conditions was received; Bulawayo celebrated the 50th anniversary of the occupation of Matabeleland. In 1944 a central African council, consultative body of Southern Rhodesia, Northern Rhodesia and Nyasaland, was formed.

In May 1946 the Howitt report on state ownership of the railways was published. (G. A. V.)

Windram, *Night over Africa* (London, 1937).

Rhodes Scholarships

Although Oxford continued to function as a university throughout the war, wartime necessities forced temporary discontinuance of the 32 Rhodes scholarships granted annually to U.S. men between the ages of 19 and 25. The group of U.S. scholars elected in 1939 did not go into residence until Oct. 1946. Elections were resumed in Dec. 1946, providing an additional 16 scholarships per year for 1946 and 1947. These 48 scholarships were divided between regular and war service candidates at the discretion of committees of selection. For war service candidates the age limit was extended and the usual restriction against marriage was relaxed. It was hoped that by this means men might compete who otherwise would have been deterred by wartime circumstances. (F. Ay.)

Ribbentrop, Joachim von

Ribbentrop (1893–1946). German foreign minister, was born April 30, 1893, at Wesel on the Rhine. Educated at a gymnasium near Metz, he went to Canada in 1910 as an independent merchant. He returned to Germany in 1914 at the outbreak of World War I. Enlisting in a Hussar regiment, he advanced to the rank of lieutenant colonel and was attached to the war ministry at the end of the

war. Following the Armistice, he returned to private business, becoming a prosperous wine merchant.

Ribbentrop joined the Nazi party in 1932 and in 1933 Hitler made him his foreign policy adviser. In 1935 Ribbentrop was promoted to minister plenipotentiary at large and in 1936 he was appointed ambassador to England. In presenting his credentials to King George V on Feb. 5, 1937, Ribbentrop instead of complying with protocol shot his arm out in Nazi salute and shouted, "Heil Hitler!" The incident caused considerable stir and amusement in London.

Five weeks before Hitler marched into Austria, Ribbentrop was made foreign minister (Feb. 4, 1938), superseding the more conservative old-line diplomat, Baron Constantin von Neurath. When Hitler occupied Austria, Ribbentrop, who was in London, assured Britain that Germany had intervened in that country only to prevent civil war; however, on March 13, 1938, he signed the law incorporating Austria into the German Reich. The German foreign minister, who endorsed Hitler's plans for eventual dismemberment of Czechoslovakia, kept in touch with Sudeten leaders, instructing them to make the Sudetenland a burning issue. After Munich, he continued to exert strong pressure on Czechoslovakia and was present at the conference on March 14–15, 1939, in which Hitler, threatening invasion, forced President Emil Hacha to submit to German occupation. After the Wehrmacht marched into Czechoslovakia, Ribbentrop signed the law establishing a Reich "protectorate" over Bohemia and Moravia.

His role in the diplomatic manoeuvring that led to the attack on Poland was both active and energetic. Entering secret negotiations with the Soviet Union, he had arranged the German-Soviet pact—the antithesis of the anti-Comintern pact he authored in 1936—and on Aug. 24, he flew to Moscow to sign the new treaty.

Ribbentrop, who was always at Hitler's side in the many conferences presided over by the German dictator in 1940, had been advised in advance of Wehrmacht preparations to attack Norway and Denmark. He also prepared official memoranda to justify the German invasions and on April 27 he exhibited what he declared to be incontrovertible evidence that Britain had planned the invasion of Norway. In 1940, he also signed pacts extending the Rome-Berlin axis to Japan and several minor satellites, such as Hungary, Rumania and Slovakia. This was Ribbentrop's year of triumph.

German military reverses later made it more difficult for him to wrest concessions from the satellite states. On Aug. 6, 1943, he unsuccessfully tried to convince Pietro Badoglio to remain with the axis. In 1944 he watched most of the smaller satellites fall away, and in 1945 he witnessed the Reich's final collapse.

After Hitler's suicide, the new Fuehrer, Grand Admiral Karl Doenitz, ousted Ribbentrop as foreign minister, May 2, 1945. Six weeks later, on June 14, Ribbentrop was captured in a Hamburg rooming house by British troops. He was indicted as a war criminal and was one of the principal Nazi defendants at the Nuernberg war crimes trial that opened Nov. 20, 1945. Found guilty on four principal counts, he was executed at Nuernberg prison on Oct. 16, 1946.

In his defense, Ribbentrop said that all the important decisions were made by Hitler and that he was such a great admirer of the Fuehrer that he never questioned the latter's motives. In a written interview given to the press (Dec. 9, 1945), he declared that he "always stood for a policy of peace," that he worked for seven years for a German-English alliance and that he opposed war with Russia.

Rice

World rice production was increasing at the beginning of the decade 1937-46 but began to decline with the outbreak of World War II in 1939. The 1936-37 production was estimated at 7,105,500,000 bu., but by 1945-46 the crop was only 6,200,000,000 bu.—a decline of nearly 20% compared with the prewar average of 1935-39. Almost all the reduction was in Asia, where 95% of the world's rice had been produced. The decline in China was particularly severe, and the production in Japan and in the Japanese-dominated countries of Siam and French Indo-China was estimated to be about 60% of the prewar level. In Japan, the crop was down to 70%. India increased rice production in 1943-44, but had always been a large importer of rice, which averaged 3,200,000,000 lb. in prewar years. The loss of imports was very serious and every effort was made to "Grow More Food." Large quantities of wheat were imported to make up for the rice shortage. The increased production in North and South America helped to meet the shortage, but it supplied only a small proportion of the world's needs.

Production in southern Europe was sharply reduced in 1942-43, most of the decline being in Italy.

The amount of rice moved in international trade declined from an average of about 13,000,000,000 lb. in prewar years to 3,500,000,000 lb. in 1944. About 90% of the prewar trade originated in Burma, French Indo-China and Siam, while exports from the western hemisphere amounted to only about 3% of the total. By 1944 the west was providing about 30% of the total exports. The distribution of rice was under the Combined Food board, and prices were controlled by government purchase arrangements.

World rice supplies were not expected to become adequate until two or three years after the war's end.

The U.S. rice-growing industry became established at a new high level in the decade 1937-46. The expansion of rice production was gradual from 1898, when the domestic crop first became equal to imports, until 1920, when the first crop exceeding 50,000,000 bu. was harvested; the latter record was not equalled again until 1937.

The acreage devoted to rice in the United States increased slowly to 1,299,000 ac. in 1920 and then continued at from about 850,000 to 1,000,000 ac. until 1937. This acreage was divided between California, with 149,000 ac. in 1937, and Louisiana, Texas and Arkansas, with 967,000 of the total 1,116,000 ac. Total U.S. acreage rose in 1942 to 1,483,000 ac. and continued high through 1946, when the record was 1,506,000 ac. Acreage and yield fluctuated widely from year to year because of the variable supply of water for irrigation and differing weather conditions at planting and harvest time. The yields in both California and the southern belt increased steadily from 1926, the gain being greater in California than in the south but with wider fluctuations, until 1941, when there was a sharp drop in both areas. In 1937 the average yield in California was 61.5 bu. per ac. and in the southern states 45.8 bu. per ac. In 1941, California's output dropped to 55 bu. per ac. and that of the south to 38.7 bu. per ac. Neither region got back to the level of 1940 by 1946. For the whole country, the average yields were: 1937, 49.1 bu. per ac., and 1946, 45.4 bu.

U.S. production increased from 53,422,000 bu. in 1937 to an average of more than 70,000,000 bu. in 1944-46.

Prices of rice to U.S. producers were fairly stable from 1933 to 1939, when a rapid advance began. California and southern rice prices followed the same general trends but were quoted differently. Southern rice returned to producers about \$2.30 per barrel of 162 lb. in 1937 and rose to more than \$6.50 per bbl. in 1945. At the same time California rice sold for about \$1.40 per 100 lb. in 1937 and \$3.50 in 1945. The average price for all areas in 1937 was 65.8 cents per bu. and \$1.78 per bu. in the high price year 1943. Exports of rice exceeded imports after 1917 except in two years—1925 and 1936. Exports increased from 11,165,000 bu. in 1937 (against 3,828,000 bu. of imports) to 17,870,000 bu. in 1943. Shipments to U.S. territories were also large. The total of shipments and exports to other countries amounted to an average of 26,400,000 bu. in the years 1940-44, compared with 22,200,000 bu. in 1937-39.

In 1937 the U.S. rice crop was divided as follows: 28,200,000 bu. for civilian consumption, 3,915,000 bu. for seed and feed, 10,730,000 bu. for export, 11,920,000 bu. for shipment to possessions and 5,290,000 bu. into stocks for carryover. By 1944 this had changed as follows: 23,590,000 bu. for civilians, 13,870,000 bu. for military and lend-lease, 4,280,000 bu. for seed and feed, 16,370,000 bu. for export and 9,990,000 bu. for shipments with only 2,570,000 bu. for stocks. Civilian consumption of rice averaged 5.7 lb. in 1935-39 and about the same in 1946, since the increased production just about met the greater demand.

Richardson, James Otto

Richardson (1878—), U.S. naval officer, was born Sept. 18, 1878, at Paris, Tex. A graduate from the U.S. Naval academy (1902), he held numerous high naval posts and on Jan. 6, 1940, was named commander in chief of the U.S. fleet. He supervised the naval war manoeuvres in the Pacific and conferred on the results of the manoeuvres with President Roosevelt in July of that year. The following Oct. he also had strategy meetings with the president, Sec. of the Navy Frank Knox and naval officials. He was succeeded Feb. 1, 1941, as commander in chief of the fleet by Rear Adm. Husband E. Kimmel.

Richardson, who retired with the rank of admiral on Oct. 1, 1942, was called back to active duty during World War II and was a member of the navy's general board, 1941-42. In May 1944, he was appointed to the joint army-navy committee investigating merger proposals. He caused a sensation at the hearings of the Pearl Harbor congressional investigating committee, Nov. 19, 1945, with the charge that he was removed from his command following a dispute with Pres. Roosevelt over fleet disposition. Richardson asserted he wanted to shift the fleet to the west coast but that the president insisted that it be kept at Pearl Harbor to restrain Japan. The admiral subsequently testified that Knox told him in March 1941 that he was relieved of his command because he (Richardson) had "hurt Pres. Roosevelt's feelings."

784 Rickenbacker, Edward Vernon

Rickenbacker (1890–), U.S. air line executive, was born Oct. 8, 1890, in Columbus, Ohio. An auto racer, he entered the U.S. army in World War I. Assigned to the air force, he was promoted to captain of the 94th aero pursuit squadron and shot down 26 German planes in battle. He was awarded the congressional medal of honour for shooting down two and routing five of seven German planes that attacked him over France in Sept. 1918. After the Armistice, he entered the motorcar business, eventually joining General Motors as an executive. Later, he became president of Eastern Air Lines, Inc.

During World War II, he went to England (1942), to study the quality of foreign aircraft in comparison with U.S. models. While flying across the Pacific ocean on a similar mission to the far east, his plane ran out of fuel on Oct. 21, 1942, and he was virtually given up for lost. After floating 23 days at sea, north of Samoa, he and his crew were picked up by a navy flying boat and brought to a base in the South Pacific for hospitalization. On recovery, he returned to the United States.

Returning to public life, Capt. Rickenbacker attracted much attention when, in an interview Feb. 14, 1943, he declared that he opposed both overtime pay and President Roosevelt's proposal that net salaries be limited to \$25,000 annually. Limitation of salaries, he warned, would shackle initiative, which he termed as "one of the great cornerstones of American business." Later that year, he made a 55,000-mi. tour of the fighting fronts which included a visit to Moscow. On his return to the U.S. in Aug. 1943, he asserted that politically the U.S.S.R. had been "constantly turning to the right."

Rickets

Rio de Janeiro

The federal capital of the United States of Brazil had an area of approximately 60 sq.mi. in 1946, within a federal district of 430 sq.mi., and a population which grew from 1,780,000 in 1937 to an estimated 1,951,900 in 1945. The city occupies a strip of land between the Tijuca mountains and the Guanabara bay and spreads up the slopes of the surrounding hills. It is governed by a mayor (*prefeito*) appointed by the president of the republic, and a federal district council elected by the inhabitants. During the decade 1937–46, Rio de Janeiro had the following mayors: Olynto de Melo (1935–38); Henrique de Toledo Dods-worth (1938–45); and Philadelpho de Azevedo (after 1945).

As the capital of Brazil, Rio de Janeiro witnessed many events of historical significance in the years 1937–46. At the end of 1937, a short-lived uprising of fascist elements gave President Getulio Vargas the opportunity to proclaim a state of war, dissolve both houses of congress and promulgate a new constitution. Vargas was overthrown by an uprising of the army in the capital during the night of Oct. 29–30, 1945; forces from Rio de Janeiro barracks occupied strategic points in the city and surrounded the presidential palace of Guanabara. A group of officers then visited Vargas and compelled him to resign.

During the Vargas regime there were many outstanding improvements of the city. A new avenue, known as Avenida Presidente Vargas, was opened perpendicular to the Avenida Rio Branco. The new thoroughfare, 260 ft. wide and about 2 mi. long, was built to serve the northern sub-

urban districts. Various new public buildings were constructed, among them the monumental ministry of war, the ministry of education and public health, the ministry of finance and the station of the central railroad of Brazil.

During World War II and as a consequence of the scarcity of gasoline and coal, the transportation facilities of the city were badly disorganized. Nevertheless, the outlying residential districts continued to develop very rapidly. With the increase of the population, to which the arrival of many wealthy European refugees greatly contributed, the housing problem became acute. New apartment houses were constructed, especially in the Flamengo, Botafogo, Copacabana, Leblon and Laranjeiras districts. Many of these buildings were owned co-operatively, and it was said that apartments were bought and sold for speculative purposes several times in succession before they were ever occupied. The prices of the apartments reached fabulous heights, four and five times the original sum.

At the end of 1946 the scarcity of foodstuffs and the high cost of living led to food riots, strikes and protest meetings of students in the capital.

On April 30, 1946, President Eurico Dutra closed all casinos throughout the country, depriving Rio de Janeiro alone of almost \$5,000,000 in yearly revenue derived from gambling, and putting an estimated 70,000 persons out of work. This action was taken because gambling, which had assumed extraordinary proportions, was allegedly taking the hard-earned money of many who couldn't afford it.

Rio de Janeiro was the seat of numerous national and international gatherings during the period, among them the Second Conference of Ministers of Foreign Affairs of the American Republics (Jan. 1942); the First Inter-American Congress of Medicine (Sept. 1946); the Second Pan American Congress of Mining Engineering and Geology (Oct. 1946). The Inter-American Conference on the Maintenance of Continental Peace and Security, scheduled to meet at Rio de Janeiro during 1946, was postponed indefinitely because of the international political situation.

Ríos Morales, Juan Antonio

Ríos Morales (1888–1946), Chilean statesman, was born Nov. 10, 1888, in Cañete, Chile. He studied law and was admitted to the bar in 1914. Four times elected to the national congress as a radical deputy, he was twice president of his party. In 1932 he became minister of the interior in the Arturo Alessandri cabinet and later was minister of justice.

He was elected to the presidency of Chile on the radical ticket in Feb. 1942, during a critical period in World War II. Although reluctant at first to break off diplomatic

relations with Germany, presumably because of his country's long and vulnerable coast line, his government finally broke with the axis on Jan. 20, 1943. He postponed a projected trip to the United States in 1942 at the invitation of President Roosevelt after Sumner Welles, then assistant secretary of state, declared that axis agents were operating freely in Chile and Argentina and were transmitting news of the United Nations ship movements to axis submarines. In a subsequent message, however, President Ríos told Roosevelt that Chile "has been and will be at every moment at the side of the democracies." President Ríos made his long-delayed official visit to the United States in Oct. 1945, visited President Truman at the White House and then toured Canada, Mexico, Central America and west coast countries of South America. He died June 27, 1946.

Ritchie, Neil Methuen

Ritchie (1897–), British army officer, was born July 29, 1897. Educated at the Royal Military college at Sandhurst, he entered the army at the age of 17 as second lieutenant in the famous Black Watch regiment (42nd Highlanders). During World War I, he served on the western front and in Mesopotamia and Palestine. Wounded in action, he was awarded the distinguished service order and the military cross.

Ritchie, who ranked as a brigadier in 1939, was an acting major general by Oct. 1940. Deputy chief of the middle east general staff, he was appointed, Nov. 26, 1941, commander of the British 8th army in Libya, succeeding Sir Alan Gordon Cunningham. In June 1942, Ritchie's armoured units fell into an ambush laid by Marshal Erwin Rommel's Afrika Korps. In the ensuing battle, Ritchie lost nearly all of his armour and his armies were battered back into Egypt. On June 25, he was replaced by Gen. Claude J. E. Auchinleck. Ritchie was a corps commander in France in 1944 and became commander in chief of the Scottish command in 1945.

Rivers and Harbours

Improvements and maintenance of rivers, harbours, and other waterways of the United States and its islands and territories for navigation, were made a function of the

corps of engineers, U.S. army, under the direction of the secretary of war and the supervision of the chief of engineers, by an act of congress approved April 30, 1824. Though work on all projects not essential to the war effort was disrupted during World War II, the ten-year period 1937–46 proved one of the most progressive decades for rivers and harbours improvements for national benefits in the country's history.

In 1936 there were approximately 1,000 river and harbour projects in force, and active operations were under way on 342 of these projects. The amount expended in the maintenance and improvement of river and harbour works for the year was \$178,829,396.50. Major projects included the canalization of the Upper Mississippi river to provide a nine-ft. channel for barge navigation; continued construction of Fort Peck dam on the Missouri river in Montana, and the Bonneville dam on the Columbia river in Oregon, both primarily for improved navigation purposes, with electric power and flood control as additional benefits; major improvements at ports and harbours on the Atlantic, Pacific and Gulf coasts, and on the harbours and connecting channels with the Great lakes; enlargement of the Cape Cod canal to a depth of 32 ft. and widths of 500 ft. and greater; widening and deepening to 27 ft. of the Chesapeake and Delaware canal to provide facilities for ocean-going vessels; the construction of new locks and dams on the Illinois waterway at LaGrange and Peoria, Ill., to insure a stabilized channel of 9 ft. in depth; and the enlargement of the New York State Barge canal to a depth of 14 ft. from the Hudson river, 187 mi. to Oswego on Lake Ontario. Equally important projects were the dredging and removal of wrecks and debris in the channels of all navigable streams.

In 1937 congress authorized 141 new projects with a total estimated cost in excess of \$50,000,000. The following year, 1938, 52 additional projects were approved and preliminary examinations and surveys were ordered at 67 localities.

In 1939 and 1941 two of the four debris dams in the Sacramento valley, authorized in 1935, were completed. Both dams were placed in use for the storage of mining debris, the North Fork dam on the American river having a debris storage capacity of 26,000,000 cu.yd., and the

Ohio river flood barrier, completed in 1939 to protect the commercial district of Huntington, West Virginia

Upper Narrows dam, a storage capacity of 118,000,000 cu.yd.

By 1940 new work was completed on 89 projects and materially advanced on 221 other projects. Maintenance operations were under way at 307 localities and expenditures during the fiscal year were \$113,200,000. Of this amount, \$70,700,000 was for new work.

In conformity with the U.S. national policy limiting wartime construction to conserve manpower, equipment and materials, the new work program for rivers and harbours after 1941 was restricted to improvements having direct importance to the war effort. However, construction essential to the prosecution of World War II was continued. For example, in 1943, improvements and maintenance operations were carried out on 323 separate projects, of which 6 were fully completed. The following new works were typical of the improvements accomplished:

The MacArthur locks on the St. Marys river at Sault Sainte Marie, Mich., begun in 1942, were completed in Aug. 1943. The installation of the initial generating unit of 35,000 kw. was completed and production of power commenced. At the Fort Peck dam, Montana, water impounded in the newly completed dam was released to augment the natural stream flow during low water periods, providing adequate channel depths for navigation; in the Missouri river and the Chain of Rocks section of the Mississippi river. Power units numbers one to eight, inclusive, were completed and placed in operation at the Bonneville dam on the Columbia river. The available rate capacity was 410,000 kw. The completed dam, navigation locks and fishways were maintained and operated during the year. The turning basin and widening of a section of the Cuyahoga river, Ohio, begun in 1942, was completed. Also completed was the west breakwater at Oswego harbour. Dredging in the Liberty Island and Red Hook Flats sections of New York harbour provided additional anchorage space. Extensive dredging operations were executed on the Intracoastal Waterway system, extending for more than 2,300 mi. along the Atlantic and Gulf coast; also at Portland harbour, Maine, in the Kennebec river, Maine, from the mouth to the ship building facilities at Bath, Me. In addition, channel and harbour improvements important to the war effort were effected on waterways and at ports on the Atlantic, Gulf and Pacific coasts, on inland rivers, and on the Great lakes.

Two special wartime projects of major character related to river and harbour operations undertaken by the

corps of engineers were the construction of a vessel fleet for the Defense Plant corporation, to augment available floating equipment for the barging of essential commodities; and the construction at Escanaba, Mich., of two large ore docks and the appurtenant facilities, for maintaining the flow of essential iron ore from the mines to furnaces.

Under an appropriation of \$4,000,000, provided in the second Deficiency Appropriation act approved July 5, 1945, advanced planning of river and harbour projects was pushed so that essential postwar river and harbour improvements could be resumed immediately upon cessation of hostilities. The total estimated cost of completing all authorized river and harbour projects determined necessary to the interest of commerce and navigation was placed at about \$581,500,000. Surveys were also completed on additional river and harbour projects, the estimated cost of the recommended work being in excess of \$2,000,000,000. The total backlog of authorized and recommended river and harbour projects was more than \$2,500,000,000.

The 1946 Deficiency bill provided \$15,000,000 for combined flood control and navigation improvement work on the Lower Mississippi river. It also provided \$25,516,000 for general rivers and harbours projects. Among the major projects begun or continued with these funds were the improvement of the Los Angeles and Long Beach harbours in California; the improvement and maintenance of the Mississippi River channel between St. Louis and Minneapolis; the improvement of the Pearl river in Mississippi and Louisiana; additional navigation work on the Missouri river at Fort Peck; continued work on the Monongahela river in Pennsylvania and West Virginia; additional work on the Great Lakes to Hudson river waterway; the improvement and maintenance of the Chesapeake and Delaware canal.

For the fiscal year 1946 congress authorized 292 new projects or modifications of existing projects at an estimated total cost of \$382,000,000. These additional improvements included a 12-ft. channel in the Intracoastal waterway from Jacksonville to Miami, Fla.; the improvement of the Apalachicola, Chattahoochee and Flint rivers in Georgia and Florida; and the development of the Alabama and Coosa rivers and tributaries in Alabama and Georgia.

The authorized navigation improvement of the Neches and Angelina rivers, Texas, provided for the construction of a reservoir in the Neches river, one in the Angelina river and two power regulating dams in the Neches river. Other rivers and harbours projects included the Guada-

Great Britain.—In the years just before World War II, ocean shipping was steadily recovering from the effects of the great damage done to it during 1914–18. While the British tonnage was not up to the older totals the average size of ships had increased and some very large ships (such as the "Queen Mary") had been built and large docks were constructed to serve them. By reason of the movement in many countries toward autarchy, foreign trade had not grown to the extent that had been hoped, but it was very considerable. International competition was keen, and the development of harbours to receive large ships and speed up their "turn-around" was pushed as rapidly as conditions permitted.

The outbreak of World War II and especially the events of 1940 transformed the situation, compelling the extemporization of additional shipping facilities in many of the ports which previously had been confined to coastal trade, throwing enormous burdens on others and greatly reducing the activities of those which were in the danger zone. Especially after the fall of France, many of the ports which had been purely commercial developed strong naval features, and all were controlled by the admiralty and the ministry of war transport. London, Southampton and Hull diminished greatly in importance while Liverpool, Avonmouth, Belfast and the Clyde ports became paramount. The larger passenger ships became troopers or merchant cruisers and the transport of cargo took complete precedence over passenger traffic, which practically disappeared except for war purposes. The heavy toll of shipping taken by submarines and mines reduced the volume of merchant shipping until the latter years of World War II but vastly stimulated the repair and new construction work of the shipyards and the demand for dry docking and slipways.

There was considerable damage to several of the harbours, especially London, Hull, Southampton and Liverpool. These changes not only affected the United Kingdom harbours directly, but by causing many activities to be shifted to the dominions and colonies (and later to the U.S.) stimulated the latter to a high degree, so that the end of the war found the United Kingdom with much reduced shipping, very small coal exports, heavily damaged port facilities, much obsolete plant and increased competition with overseas ports. The loss, however, was partly offset by additional wharfage and wharf equipment, and even by

Section of a prefabricated harbour under construction at Southampton, England, early in 1944. The harbour was later transported for use in Normandy, France

new ports specially constructed to deal with military cargoes and the oil jetties and pipe lines which enabled petroleum products to be loaded at convenient points whence they could be pumped across country.

The climax of British home port operation during World War II was the operations of D-day in June 1944. The prefabricated ports ("mulberries") were prepared in British harbours, assembled and dispatched from British harbours; one-half was assembled, controlled and operated in Normandy by men whose experience had been gained in British harbours. The most novel feature of these harbours, which might well take a place in commercial harbour practice, was the spud pier pontoon. The spud pier

consisted of one or more pontoons, each of which rested on the sea bed through four massive steel "spuds" (four sq.ft.) which could be raised or lowered by winches operated from diesel electric plant installed in the pontoon. This system, long used for certain types of dredger, enabled the pontoon to be firmly anchored and adjusted as to height so that it had the portability of an ordinary floating pontoon and the rigidity of a fixed pier but without the variable "freeboard" of the latter. In the "mulberry" set-up there was about 18 ft. of water alongside at low tide, and as the tide might rise as much as 23 ft. there was about 41 ft. at very high water. The pontoons were connected to one another and to the shore by flexible bridges. The "phoenixes" or concrete caissons which were floated into place and sunk to form breakwaters were only novelties from a harbour engineering point of view in respect to the speed and magnitude of their use. Many of the British harbours were provided with special loading "hards" for the accommodation of beach landing craft, and it was possible that some of these might have a future commercial application.

After the end of World War II, shortage of labour and the uncertainties arising from the government's nationalization policy prevented much from being done to restore and improve home ports or to realize the programs drawn up by the various port authorities, but a vigorous start was made.

British Commonwealth.—The harbours of the British dominions and colonies (over 200 in number) were greatly stimulated by World War II. Major dry docks were built in South Africa (Capetown) and Australia (Sydney), which enabled the largest ships afloat to be repaired in those countries, and in all the lands of the commonwealth, the harbours increased their equipment of docks (dry or floating), slipways, wharfage, craneage, warehousing facilities, berthage, rail connections and organization. Furthermore Canada, South Africa, Australia and New Zealand all developed their industries to a degree which rendered them to a considerable extent independent of United Kingdom resources.

While the harbours of Hong Kong, Singapore and Rangoon suffered to some extent from war damage, neglect and Japanese occupation, they were all rapidly recovering their physical conditions. Their political futures were somewhat obscure, and it might be reasonably supposed that no large developments would take place there for some years, but as they were all fairly well equipped in 1939, the repair of war damage put them back to adequate capacity. In India and Ceylon all the harbours were very active during World War II, and there was a certain amount of development. Thus the port of Vizagapatam was able to advance part of its prewar scheme for expansion, Colombo acquired a new graving dock and certain other useful additions, and slipways and repair facilities generally, which were always inadequate in Indian ports, expanded appreciably. Bombay, tremendously overloaded with shipping during the war, suffered seriously in April 1944 from the explosion of a munition ship, but made a good recovery. Aden had enormous additions made to its mooring areas, and breakwaters were built which gave still better shelter. Improvements and additions were made in Mombasa, Durban, East London, Freetown and Takoradi and to all the major ports of Canada. In Canada, extensive construction of new ships and repair of damaged ones was undertaken, and the facilities created for this work were to remain actually or potentially for peacetime use.

The major graving docks built during the war period in Capetown and Sydney were of special importance. The first was typical of the requirement which was now considered necessary in a first-class harbour. It had an effective length of 1,212 ft., a width at 34 ft. below low water of 136 ft. and a depth over the sill at high water of 45 ft. 9 in. It could be divided by an intermediate caisson into two basins, and there were alternative positions for this caisson. It led off a new wet basin 6,000 ft. by 2,000 ft. with 40 ft. depth at low water and berthage for 14 large ships, and had 2 double-storey sheds 500 ft. by 120 ft. with 3-ton roof cranes and 5-ton lifts. In several commonwealth ports there were opportunities for the authorities to acquire floating docks which had been constructed for naval purposes.

Europe.—The harbours of continental Europe presented a sad picture in 1946. With the exception of ports in Spain, Portugal and Sweden, most of them (there were something like 300 open to foreign trade) suffered some damage and many received grave injury. In addition, owing to political complications, many were working on only a very limited scale. The vast nexus of rail, canal and air communications had been disrupted by war damage, or military barriers. Repairs were mostly of an improvised character, operation was still under military control throughout large regions, ship repairs and facilities were scarce, iron and fuel supplies were scanty, and the whole shipping situation was dominated by the problems of distributing the indispensable minima of food and other essentials of life.

It seemed useless in 1946 to discuss the future of the German ports, but their rehabilitation was proceeding and the inland waterway system to which they are related was slowly recovering. The suicidal policy adopted by the Germans before surrender, of destroying bridges and canals, had proved a grave hindrance, but the great improvising skill developed by military engineers had prevented a complete collapse of communications. Information as to the actual conditions of the ports in eastern Europe was lacking, but sufficient was known to indicate that conditions there were much the same as in Germany.

In western Europe recovery was more marked, and many of the harbours were functioning as well as could be expected in the circumstances. Warehousing accommodation was particularly short, and the housing of port workers was still a serious matter. The great ports of Belgium and the Netherlands were returning steadily to normal. The great lock at IJmuiden was being repaired, but there was still much to be done to clear obstructions. Copenhagen was practically undamaged. The Rhine had been opened again to through navigation.

Probably the greatest hindrance to port recovery in Europe was the political barrier. A great harbour is dependent for its very existence on good communication with a large hinterland and linkage to an extensive system of overseas harbours, or in the case of an *entrepôt*, free connection with a double set of overseas harbours between which it is the linkage point. Unless physical and commercial connection between the harbour and its sources and delivery points is free, or at least consistently and satisfactorily regulated, the prosperity of the harbour can not occur. The disputes concerning the political future of Trieste illustrated this point. Internationalization of contested ports might be a *pis aller*, and undoubtedly lead eventually to other problems (as had been the case for example with Egyptian and Chinese harbours) but it did appear to be the only solution of a practical character where conflicting national aspirations were irreconcilable.

Sunken bridges, damaged locks and stalled vessels made a bottleneck of the Danube canal near Vienna after the battle for the Austrian capital in 1945

France suffered particularly from damage to her harbours during World War II. Practically every port was affected, Marseilles coming off the best. Brest, Le Havre, Bordeaux, Rouen and Dunkirk were all heavily injured and by 1946 had made only slight recoveries. Not only were the port installations destroyed, the approaches blocked with wrecks and mines, and equipment ruined, but all the rail and road system was injured for many miles around.

Following the Allied invasion in 1944, military resources enabled some ports, such as Calais and Cherbourg, to be brought partially back to use, but in 1946 there were still grave shortages of wharfage, storage accommodation, housing and other facilities.

Italian ports were heavily bombed, Genoa, Leghorn and Naples suffering most. In Greece, shipping was handicapped by the blockage of the Corinth canal.

The strategic importance of harbours was emphasized once again by the events of World War II. The invasion of the continent was practically impossible until the artificial harbour scheme had been devised, while the last struggles in the west revolved about Antwerp as a supply point for the armies of the Allies.

Certain other lessons sprang from World War II. It was found possible to make temporary repairs to wharves, docks and other harbour features far more rapidly than had been anticipated, and the flexibility of motor transport by road, or if necessary by tracked vehicles made it possible to keep a port in operation in conditions which would have seemed quite impossible some years earlier. These were not very consoling features in the face of the great damage of modern war, but they at least showed that technical development had a positive as well as a destructive side. It had also become apparent that there

was a need for a more intimate interest to be taken in the housing and welfare of harbour employees, not only for humanitarian reasons but also for the very efficiency of the harbour operations. The damage done to the residential areas occupied by dock workers in London and Hamburg proved nearly as injurious to the working of those harbours as the direct destruction of facilities in the harbours themselves.

Technical Aspects.—No very remarkable features of harbour technique appeared in 1937-39, but the war did bring forth a number of inventions, some of which would perhaps affect future practice. The most significant of these were radar and asdic, which respectively enabled ships to find one another in fog and to discover underwater features. Radar could of course also be used for traffic control, and considerable attention was being given in 1946 to its peacetime applications. Echo-sounding (of which asdic was an extension) was now very extensively used for harbour surveys as well as for deep-sea work. Amphibious craft proved so useful in the war that it was thought they might come into rather wide use for the discharge of small vessels in minor harbours. Pontoons, floating docks and other harbour craft were made during the war of steel units bolted together, but it was not considered probable that these would be adopted as permanent features in harbour practice. The flexible landing bridges which connected the spud piers to the shores in the "mulberry" harbours were also not thought likely to be applied to commercial harbours.

Wharf design had been very thoroughly studied in the years between World Wars I and II. The slab and pile construction increased in popularity for poor foundation conditions and high wharves. A "bell" type of fender for dolphins was found to be very successful in protecting ships and dolphins from mutual damage. Dredging technique showed few changes. The use of large seagoing

suction-hopper dredgers increased, but the number of new vessels built between 1937 and 1946 was quite small, and little had yet been done in Europe or the dominions to adopt the Franco-U.S. type of suction dredger with side flexible pipes.

Some of these vessels, however, were seen working in European waters, and it was probable that their advantages would lead to their adoption.

An interesting feature was the growing practice of using tidal models of harbours before embarking upon new designs. Not only in respect of the stilling of waves and the control of currents could such models give valuable forecasts, but also in regard of accretion or scour. The technique of such models was elaborate, and practical experience was necessary to the proper interpretation of their results.

Scientific investigation of waves, beach formation and erosion and tidal currents made considerable progress during 1937-46, especially during World War II. Devices such as floating breakwaters, etc., received an unusual amount of attention and there could be little doubt that the technical information which had become available to harbour engineers would show later in novel and valuable features. (See also AQUEDUCTS; CANALS AND INLAND WATERWAYS; DAMS; FLOOD CONTROL; TENNESSEE VALLEY AUTHORITY.)

Roads and Highways

At the beginning of the decade 1937-46, the outlook for highway improvement throughout the world was promising. The dependability of automobiles, trucks and busses, as instruments of transportation had been demonstrated for many years, but, in most countries, the full service to be obtained from these vehicles when complemented by an adequate system of highways was just being realized to an extent that stimulated action. Less developed countries were accelerating the initial construction of highway systems, and those with old systems were considering or beginning the modernization of obsolete roads to make them suitable for safe and rapid movement of large volumes of traffic.

In 1937, 1938 and 1939 there was every indication that the greatest highway construction program in history was developing throughout the world. Then came World War II, and normal highway construction ceased in the countries at war and was seriously checked elsewhere. A few notable highways such as the Alaska highway and the Burma road were built as war projects, but the most significant effects of the war on highway transportation was the halting of new construction and the great destruction of highway surfaces and highway bridges in combat areas. Roads and bridges destroyed in Italy, France and Holland would take years to replace.

The end of the war was followed by immediate and world-wide interest in highway improvement. Ambitious prewar plans were revived and enlarged. Depleted resources, political unrest and uncertainty and readjustments from war conditions prevented large construction programs, but planning was conducted on a scale that promised great activity in future years. The people of the world desired peace and prosperity, and it was realized that good highways would be necessary for industrial, agricultural and social development.

A considerable mileage of highways was constructed in the 10-year period, but disruption of normal reporting

services during the war prevented any estimate of the amount. The most important progress made was in the adoption of new concepts as to the character of highway improvements needed and in action by many different groups in almost every country to stimulate highway development.

Technical Progress.—Good progress was made in improving methods of highway construction, but it consisted of improving ways of using known materials rather than discovery of new products.

Marked advances were made in preparing mixtures for both concrete and bituminous road surfaces. In some parts of the world there are aggregates that, when used in concrete, cause disintegration. Other aggregates do not retain a coating of tar or asphalt and also cause disintegration. Laboratory research developed methods of identifying such aggregates and the procedure to be followed to avoid road failures. New materials were developed for addition to cement or to concrete mixtures that materially increase the durability of concrete.

For many years highway engineers sought to avoid road failures resulting from placing surfaces on clay and other unfavourable soils. They also sought to combine local materials such as sand and gravel with a binder such as clay or bituminous materials to make a low-cost road surface. They studied soils to devise ways of compacting fills to avoid the cracking and breaking of road surfaces resulting from settlement extending over a period of years. A science of soils for application in highway work was developed. Practical application of soil science increased greatly after 1937. Soils laboratories were established, and construction engineers applied the knowledge gained in research laboratories.

During the war this knowledge was of great importance in building military airfields and roads in all parts of the world.

Demonstration of the practical results of highway research gave impetus to this work. In the United States, research by state and federal agencies was directed to war purposes until near the end of 1945 and was then reoriented to solve the problems of a large peacetime program. In England, the local authorities and engineers responsible for highways became increasingly research-minded, largely through the leadership given by the road-research laboratory of Britain's department of scientific and industrial research at Harmondsworth near London. Brazil established laboratories at Rio de Janeiro, and Argentina continued work on its special road problems.

At the beginning of the war, the research establishments of Germany and France were among the important contributors to highway knowledge. The organization in Germany was destroyed, and the work in France received a serious setback.

Development of the diesel engine produced important results in highway transportation. This engine had been invented years before, but marked improvements in efficiency and reliability resulted in a widening of the field of use during the decade 1937-46. Diesel-powered bulldozers, graders, shovels and trucks made possible the moving of the great quantities of earth necessary in modern highway construction. With less efficient machines it would have been necessary to make some sacrifice in standards for width, grades and directness of highways. The num-

Four-lane Pennsylvania turnpike, built at a cost of \$70,000,000 and opened to traffic Oct. 1, 1940. The maximum grade of this 160-mi. superhighway through the Appalachians is 3%; there are no crossings, and cars can take all curves at 90 m.p.h.

A six-lane express highway, opened June 30, 1939, forms the New Jersey entrance to the Lincoln tunnel, which extends under the Hudson river to New York city

ber of trucks and busses driven by diesel engines increased greatly.

The bulldozer and other equipment developed for highway purposes were important tools in winning the war. They were used by U.S. forces to build landing fields for aeroplanes in a few days where Japanese methods would have required months.

Express Highways.—In 1937 the German system of *autobahnen* and the Italian *autostrade* were the best known examples of modern highways built for rapid and unobstructed travel of automobiles. The United States had preceded Germany in developing four-lane divided highways for free movement of large numbers of vehicles, but the highways constructed were short in length. In 1937 the Pennsylvania turnpike, a 160-mi. highway linking Harrisburg and Pittsburgh in the eastern part of the United States, was authorized; it was completed in 1940. By 1944, the United States had over 6,000 mi. of primary state highways with four or more traffic lanes, but many of these were not divided to separate opposing streams of traffic, and in many instances frequent intersections with other highways at grade prevented the highways from having true express characteristics.

There were more than 1,000 mi. of highway to which access was permitted only at selected points some distance apart.

Experience in England and the United States demonstrated the necessity of controlling access to routes built for express traffic movement. Wide highways were built leading out of cities to accommodate fast-moving traffic, but businesses and dwellings were placed fronting on these highways which were soon converted to local business streets.

It was found that this could be prevented only by placing the highway on a wide right-of-way, permitting access only at selected points and constructing parallel roadways to serve local traffic movement.

Notable multiple-lane highways were built in a number of countries. Canada completed a divided highway from Niagara Falls to Toronto. In 1940, Brazil began the construction of a 35-mi. divided highway beginning at the port of Santos and climbing an escarpment to São Paulo. Broad, modern highways were constructed at Buenos Aires, Argentina, and Rio de Janeiro, Brazil. England actively planned a 1,000-mi. system of motorways, but the war

prevented the beginning of construction. At the beginning of World War II in 1939, France was constructing a 19-mi. divided highway with controlled access from Paris toward Normandy and Brittany. Work stopped during the war, but the highway was completed soon after the war ended.

During the 10-year period, highway design grew up and matured. As exemplified by the best highways in several countries, modern motorway design involved a number of features, varying combinations of which were found in the better roads constructed to carry a large traffic volume.

The more significant features were: exclusive right-of-way with prescribed points of entry and exit, the number varying with the environment and type of facility; separation of opposing traffic by an unpaved dividing strip; separation of fast from slow traffic by means of separate lanes for each; easy curvature; low gradients; adequate pavement capacity; land service roads where necessary; elimination of all railroad, street or highway crossings at grade; hard surface pavements; adequate landscaping; and provision for incorporation into the roadway design of abutting service facilities, such as gasoline stations and parking areas.

The United States designated and began construction of a 40,000-mi. national system of interstate highways. Much of this system was to be improved as four-lane, divided highways without intersections at grade with other transport arteries. The work was undertaken as a postwar project.

Bridge Construction.—Considerable progress was made in replacing old and obsolete bridges with structures of sufficient width and strength to accommodate modern traffic. Many new bridges were required to separate grades at intersections with other highways and rail lines. Welding came into more general use, as did the types of bridges known as rigid frame and continuous span. (*See also BRIDGES.*)

New Highways Through Undeveloped Regions.—Construction of roads of great length through remote wilderness areas far exceeded that of any other ten-year period in history. In the spring of 1942 the United States, after agreement with Canada, undertook the construction of a road from the railhead at Dawson Creek, British Columbia, to a junction with the Richardson highway at Big Delta, 100 mi. from Fairbanks, Alaska. This highway, through 1,420 mi. of wilderness in a subarctic region, through mountains and across muskeg swamps, permanent-

ly frozen ground and many large streams, was built for the defense of Alaska and to develop an air route to the U.S.S.R. During 1942 army engineer troops and civilian forces directed by the Public Roads administration forced through a pioneer road. Army forces were withdrawn from highway construction early in 1943. During the following months 15,000 civilian workmen completed a highway suitable for use as an army trucking route. Completion was in Oct. 1943.

Following occupation of the seacoast of China by Japanese, intensive efforts were made in 1938 and 1939 to build supply routes from interior China to the outside world. Highways were built to French Indo-China and the Soviet Union. The most notable effort was construction of the 610-mi. road from Chungking through a mountainous region infested with malaria-carrying mosquitoes to Lashio in Burma. This highway, called the Burma road, attracted world-wide attention in 1940, when it became a Chinese life line.

In 1940 work was begun on a 621-mi. highway across the so-called "dead heart" of Australia in order to move military supplies to the important base at Darwin on the north coast of Australia. The highway was opened to traffic in 1941.

In 1945 a 478-mi. road from Ledo in northeast India to a junction with the Burma road near the Chinese border was completed as a military project.

This road through mountains and tropical jungles was built with great difficulty to reopen a wartime supply route to China.

Many improvements were made on the Pan-American highway extending from the southern border of the United States through Central America, down the west coast of South America and across to Buenos Aires and Rio de Janeiro. The section of this route north of Panama was also known as the Inter-American highway. Important construction was done in Mexico, all of the Central American countries and in Ecuador and Peru. By 1946 tourist travel from the United States to southern Mexico was pos-

Heavily wooded areas being cleared for the Alaska highway in 1942

All traffic on the Alaska highway was recorded on this control board at the headquarters of the U.S. Army Northwest Service in Dawson Creek, B.C. Supply convoys to U.S. northern outposts rolled steadily over the highway during World War II

sible. Much of the route beyond had been improved and was being used by local traffic, and in several places for travel between countries, but impassable jungles or mountainous areas not penetrated by roads prevented tourist travel. Of the 3,279 mi. from the United States to Panamá City, 2,566 mi. could be travelled in all weather, 303 mi. could be travelled in dry weather only, and there were 410 mi. of impassable gaps. Between the Canal Zone in Panamá and the Panamá-Colombia boundary there was an impassable gap of about 300 mi. Of the 8,097 mi. in South America (alternate routes included) 6,162 mi. were surfaced, 1,646 were passable in dry weather, and impassable gaps amounted to 289 mi.

War Damage.—Destruction of highways, particularly bridges, reached a peak in 1945. In 1944 and until May 1945, as the Germans were driven from large areas in the U.S.S.R., Italy, France, Belgium and Holland, they destroyed practically all bridges behind them. Every bridge and culvert between Rome and Naples, about 1,200 in all, was blown up. About 6,500 bridges in France were destroyed. Numerous magnificent bridges across the Rhine were wrecked. In Holland, 30 large bridges and over 1,000 small ones were destroyed. Nowhere did the destruction exceed that of the many bridges on the system of *autobahnen* in Germany.

In the Philippine Islands, war damage and neglect of highways caused a loss amounting to 35% of the prewar value of the highway system. Of 1,741 permanent-type bridges, 621 were destroyed. In 1945, the U.S. Army provided temporary structures crossing more than 200 streams, and in 1946 the United States allocated nearly \$10,000,000 and provided engineers to assist the Philippine government in rehabilitating its highways. Intensive replacement of the destroyed structures was under way in 1946 in all war-damaged countries.

U.S. Highway Construction.—In the period from Jan. 1, 1937, through 1945, 222,000 mi. of surfaced highway were constructed in the U.S., of which nearly 70% consisted of

Aerial view of the Stilwell road, built to link India and China at a cost of \$148,910,000. It was declared surplus property by the U.S. army on Nov. 6, 1945

primary state highways. Most of this work was improvement of existing highways and only about 5% was on new location.

Motor vehicle registration increased from 30,041,000 in 1937 to a peak of 34,854,000 in 1941 and was estimated to be 32,511,000 in 1946. In each year of the 10-year period, highway users contributed in the form of gasoline taxes, registration fees and other special taxes more than \$1,000,000,000 for highway purposes. In 1941 the contribution was \$1,452,000,000.

Expenditures for highway construction, maintenance and debt were more than \$1,000,000,000 each year, amounting to \$1,538,000,000 in 1941.

Rockets

It is necessary to distinguish between rockets as complete projectiles, comprising fuze, war head, rocket body and fins and rocket propulsion units, which constitute a source of power used in many different applications, among which projectiles represent one class. It is customary to refer to the propulsion unit as the rocket motor. Its basic characteristics remain the same, whatever its purpose, but constructional details are varied to suit specific requirements. The outstanding common characteristic of rocket motors, whether for projectiles or power units, is the development of thrust for a limited time, and in every practical application of rocket technique minimum weight is a paramount consideration. Depending on the purpose for which the motor is required, greater or less complexity may be incurred, and when intended for repetitive use as in assisted take-off or propulsion of aircraft it must be durable, and the thrust must be precisely controlled to avoid overstressing of aircraft structures. In aircraft propulsion, controlled flexibility of thrust during operation is required,

but in projectile applications where consistent ranging is important, the total impulse delivered (thrust \times time integral) is more important than the precise value of thrust or duration taken separately. In projectile applications where maximum range is required, ballistic shape is important, and a long, thin rocket is usually implied. Where extreme accuracy of flight is sought, control should be invoked; but if this is impracticable, great attention must be given to accuracy and rigidity of construction at certain essential points in the rocket.

Uses and Characteristics.—The following list includes examples typifying the salient characteristics of rockets:

(1) Rocket propulsion of aircraft. The first example was the German Me. 163, using hydrogen peroxide (80%) as oxidant, and a mixture of methyl alcohol and hydrazine hydrate as fuel. Hydrazine hydrate induces spontaneous inflammability of the fuel. The rocket motor was developed by Dr. H. Walter at Kiel about 1942-43. Best models incorporate main and pilot combustion chambers for climb and cruising respectively. Combustion chambers are liquid-cooled by fuel to counter high combustion temperature.

(2) Assisted take-off of aircraft. Many different types were designed and used during World War II in the U.S.A., Britain and Germany, employing solid and liquid fuels of several natures with duration from 4 sec. to 60 sec. and thrust from 1,000 to 6,000 lb. These were of particular use for heavily laden aircraft or where take-off distance was restricted, as in small airfields or aircraft carriers.

(3) Auxiliary motors in aircraft. An obvious application, contemplated by many designers, was to provide exceedingly rapid climb or speed-boost for limited period.

(4) Line throwing for lifesaving, climbing, river crossing and the like; projection of nets, grapnels and ladders; erection of wire barrages to counter low-flying aircraft. In cases where the line is light in weight or the object to be thrown is massive, a short rocket-burning time is permissible providing snatch on the line is avoided. In this case the momentum of the rocket or, e.g., the grapnel is sufficient to unspool the main run of line. Longer burning time is necessary for nets or similar objects where the main weight is distributed over the thrown length.

(5) Large long-range projectiles. The first example was the German V-2, used in World War II. The payload was 1 ton (normally a war head filled with high explosive). Design range was 190 mi. It was propelled by bifuel unit employing ethyl alcohol and liquid oxygen. Total weight unfuelled was 4 tons; fuelled, 12 tons. Fuels were delivered by 2 centrifugal single stage pumps driven by 550 h.p. impulse turbine employing steam generated at 20-30 atmospheres by catalytic decomposition of hydrogen peroxide. Stabilization was accomplished by four large fins at the tail, and the trajectory was controlled by four graphite rudders in the jet stream together with four control vanes at the extremities of the fins. Movement of the internal rudders and the vanes was by electrically driven servo-motors, monitored by gyroscopes. Velocity was controlled by a fuel cutoff, operated by integrating an accelerometer or ground

radio signal.

(6) Recoilless armament for aircraft. This application was used by all four major belligerents in World War II. Complete absence of recoil (when fired from an open-ended projector) permitted the use of large calibre rockets without stressing aircraft structure. Special problems were encountered with unguided rockets in connection with sighting, owing to curvature of the early part of rocket trajectory and sensitiveness of the rocket to direction of launch relative to instantaneous flight path of aircraft. Larger types were fitted with wings and guided to the target by radio link or wire link from the parent aircraft. A special case was the rocket-assisted bomb, where rocket motors were employed to obtain high striking velocity (hence deep penetration) when bombing from relatively low heights for greater accuracy.

(7) Massed fire on land or sea. Absence of recoil permits multi-barrel rocket mountings on light, easily transportable carriages, or large multiple banks of projectors in ships.

Solid and Liquid Fuel Motors.—There is an obvious classification of rocket fuels into solid and liquid types, and it is instructive to study the characteristics of these two natures of propellant on a comparative basis. The fundamental difference between them rests in the fact that the solid propellant has geometrical shape and, since burning takes place on its surface, the rate of burning of a solid charge is dependent on its shape. Other factors are influential, particularly chemical composition, combustion pressure and the initial temperature of the charge, but these factors are also important with liquids.

It is generally a requirement that the thrust delivered by a rocket motor should be substantially constant or, alternatively, that it should be amenable to controlled variation. Except in cases where the requisite variations

Official British version of the V-2 stratosphere bomb. (1) chain drive to external control vanes; (2) electric servo-motor; (3) burner cups; (4) alcohol supply from pump; (5) air bottles; (6) rear joint ring and strong point for transport; (7) servo-operated alcohol outlet valve; (8) rocket shell construction; (9) guiding equipment; (10) pipe from alcohol tank to warhead; (11) nose fitted with switch for operating warhead fuse; (12) conduit carrying wires to nose of warhead; (13) central exploder tube; (14) electric fuse for warhead; (15) plywood frame; (16) nitrogen bottles; (17) front joint ring and strong point for transport; (18) pitch and azimuth gyros; (19) alcohol filling point; (20) double-walled alcohol delivery pipe to pump; (21) oxygen filling point; (22) concertina connections; (23) hydrogen peroxide tank; (24) tubular frame for holding turbine and pump assembly; (25) permanganate tank; (26) oxygen distribution from pump; (27) alcohol pipes for subsidiary cooling; (28) alcohol inlet to double wall; (29) electro-hydraulic servo motors

are to be repetitive from one unit to another, solid fuel rockets are not amenable to substantial thrust variation, since the rate of burning at any stage is predetermined by the original geometric shape of the charge. Thus, the most frequent use of solid fuels is in applications where approximately constant thrust and, therefore, constant burning surface is desirable. The number of geometric shapes capable of meeting this requirement is limited. In cases where no attempt is made to restrict burning at any point on the surface, a simple tubular shape is suitable, and constancy is secured by the fact that the outer surface decreases as the inner surface increases. An alternative, where it is necessary to prevent burning on the outer surface of the charge, is to employ a star-shaped inner section. Then, as burning proceeds, the star section progressively deteriorates into a circle, and by proper design an approximately constant surface is retained.

These two methods are typical for rocket motors in which a relatively large burning surface is required. It is, of course, possible to use multiple charges comprising, for example, a bundle of tubes or a tube inside a star section. A third method is available for cases where a relatively small burning surface is required, which might be to suit a high rate of burning, or to obtain a long period of burning. This method consists in using a solid charge, protected on its outer surface to prevent burning there, and burning only from the end surface, cigar-wise.

A serious restriction with solid charges is now apparent. The characteristics of a rocket motor are broadly defined by (1) thrust; (2) duration; (3) length to diameter ratio and (4) weight. The possibility of meeting any specified thrust and time requirements depends on the characteristic rate of burning of the proposed fuel, and on the burning sur-

face and "web" thickness which can be made available together. Basically there are only two arrangements of the charge, one where the direction of burning is perpendicular to the charge axis, on a surface approximately equal to its outer surface area; the other where burning is parallel to the axis on a surface approximately equal to the cross-sectional area. There is no simple means of achieving a gradual transition between these two systems.

No such restriction exists with the liquid-fuel system since, without variation in the intrinsic rate of burning of a fuel, any desired rate of consumption can be arranged by suitable design of feed rates and combustion chamber. This is the fundamental difference between solid and liquid fuel systems. There are, in addition, many ancillary differences.

Stabilization and Weight.—An unguided rocket projectile consists of the rocket motor, the payload, and the fins (if they are employed). Alternatively, the rocket may be spin-stabilized like a normal artillery shell, and in this case fins are unnecessary. The choice between fins and spin for stabilization depends on the characteristics sought in the projectile. Generally speaking, fin stabilization is desirable in high performance rockets, but the fins are usually a nuisance in handling and packing, and a spin-stabilized rocket is preferable from the point of view of convenience. It is, however, impracticable to provide the excessively high rates of spin which would be necessary to stabilize a long, thin projectile; and in all cases where spin is employed there is some sacrifice of forward velocity on account of jet energy employed to develop spin.

A guided or controlled rocket projectile must carry an appreciable weight of apparatus which competes against the useful payload in the total carried weight. On general grounds it is clear that this tends to make small guided projectiles uneconomic on weight considerations but, when occasion demands, control apparatus can be made surprisingly small and light in weight. It is probably true to say that, except for the very smallest rocket projectiles, the weight of control apparatus is not a prohibitive factor. For projectiles required in very large numbers, however, the cost of control apparatus may be a determining point. Moreover, since there are obvious difficulties in controlling several projectiles concurrently, it may be useless to consider such cases for control.

Rockets in World War II.—Widespread interest in rockets and jet propulsion had grown up in the early '30s. In 1933 the rocket experimental station in Berlin was already a well established concern, developing a rocket stabilized by one large gyro in the nose. In 1934 the gyro having now been shifted to the centre, the rocket was successfully launched on a flight of 2,000 m. By 1938 a projectile similar in shape to the V-2 and about 25 ft. long, with automatic steering and rudders in the gas stream, was launched vertically in the manner eventually adopted for V-2. This projectile had a range of some 11 mi.

In Great Britain the revival of official interest began in 1936, when Sir Alwyn Douglas Crow was appointed to take charge of rocket development. In early 1939 a large-scale ballistic trial of his 3.25-in. anti-aircraft rocket was carried out secretly in the British possession of Jamaica, chosen because clear skies were needed to permit observations of the rocket shell-bursts at high altitude. Several million rockets of this basic design were manufactured in Great Britain for use in World War II for anti-aircraft purposes and, in a slightly modified form, for firing from aircraft and for use on land as medium range artillery. This 3-in. U.P. (un-rotated projectile) was the first rocket weapon used by the Allies, but it was the forerunner of scores of

Inspection of a German V-2 rocket before it was launched at U.S. army ordnance proving grounds, White Sands, N.M. Fired on May 10, 1946, it rose almost 75 miles in the second of a series of tests under the long range guided missiles program which included investigation of the ionosphere

The Mark-102 rocket launcher, operated automatically and capable of firing forty 5-in. rockets per minute, being demonstrated at Dahlgren, Va., in May 1946

others developed by all the major belligerents. The advance, which it typified, lay in the use of extruded cordite for the propellant charge instead of gunpowder, which had been the most powerful solid rocket propellant available up to that time. It permitted the design of much larger and more powerful rockets with much greater velocity and range.

It is impossible to overlook the importance of the German V-2 as a landmark in rocket development. It was preceded, it is true, by the V-1, launched against London from the German-occupied French coast from June 13, 1944, in increasing numbers until the Germans had been driven from all convenient launching points. But the V-1 was not a rocket; it was an expendable pilotless aircraft, powered by a sub-sonic propulsive duct consuming petrol and atmospheric air. Its speed was in the range of 300-400 m.p.h. and it was, therefore, vulnerable to fighter aircraft and anti-aircraft shells. Its relatively small size (17 ft. wing span and 22 ft. fuselage), combined with its high flying speed, made it a difficult target, but toward the end of the period of its large-scale use by the Germans a very high percentage of the missiles launched were shot down before reaching their target.

Not so with the V-2; carrying the same weight war head of nearly 1 ton, to a range of 190 mi. in a time of flight of 5 minutes, nothing could be done to deflect or hinder it once it had been launched. Its firing site required little

preparation; essentially it needed no more than a 25 ft. square of hard level ground with road access. The rocket rose vertically and could be fired equally easily from the middle of a wood or from the open road. Within three hours of its first arrival on the site, the rocket could be fired and the site cleared, leaving no visible trace.

Disadvantages of the V-2 lay in its relative complexity and the large production effort needed to achieve the result. But it must be remembered that when it was used by the Germans the V-2 had hardly completed its development. It should be considered as only the forerunner of much more ambitious proposals, outstanding among which must be contemplated a piloted projectile fitted with retractible wings to be put out at the vertex of its trajectory, enabling it to glide hundreds of miles and land at its destination.

Postwar Developments.—A technical mission under the direction of Lieut. Gen. J. F. Evetts left England for Australia in April 1946 to explore the practicability of employing large tracts of waste land and desert there for rocket-firing trials. At White Sands, N.M., U.S. scientists fired V-2 rockets, assembled largely from parts recovered in Germany, to heights of over 100 mi., creating new altitude records. Recording and telemetering instruments, carried in the war head compartment, provided valuable new data concerning many meteorological problems. Other guided missiles, developed at the California Institute of Technology under the leadership of Dr. Frank J. Malina, were successfully fired and demonstrated the remarkable rate of technical progress in rockets achieved in the U.S.A.

A large experimental establishment was installed at Westcott aerodrome, near Aylesbury, England, for guided projectile research, under William R. Cook. (See also JET PROPULSION; MUNITIONS OF WAR.)

Rodriguez, José Maria Caro

Cardinal Rodriguez (1866–), Chilean prelate, was born June 23, 1866, in Cahuil, Chile. Educated at the Santiago seminary and the Gregorian university, he was ordained at Rome in 1890. He was vicar apostolic of Iquique, the mining section of Chile, bishop of La Serena (1927) and archbishop of Santiago (1939). As ordinary of the Chilean capital, he maintained friendly relations with the government and furthered its social plans but kept aloof from political entanglements. He was host to churchmen from all the Americas who attended the Chilean National Eucharistic congress in 1941. Nominated to the Sacred College of Cardinals in Dec. 1945 he was created a cardinal at the consistory in Rome, Feb. 18, 1946. As illness prevented his attendance at the February rites, he received his red hat at a private consistory in the Vatican on May 17, 1946.

Rokossovsky, Konstantin

Rokossovsky (1887–), Russian army officer, was a major in the tsarist armies that fought against the Germans during World War I. After the revolution, he joined the bolsheviks and saw action in the civil wars, 1918-20, and in the Russo-Polish campaign of 1920. During the peaceful interim between World Wars I and II, he was sent to the Frunze Military academy where he studied tank and air warfare. In World War II, he commanded one of the seven soviet armies defending Moscow in 1941. He also participated in the battle of Stalingrad, 1942-43, where he was in command of the 6 soviet armies of the Don front that trapped and annihilated the 22 divisions of the German 6th army.

During the soviet offensives in 1943 and 1944, Rokossovsky headed an army on the central front and played an important role in ousting the German forces from White Russia and eastern Poland. He led the 2nd White Russian army that broke through German defenses south of Lomza and subsequently destroyed German resistance in Stettin, West Pomerania and Mecklenburg provinces.

Roman Catholic Church

The pope is recognized as supreme ruler and pastor of the Roman Catholic Church. It is he who creates cardinals, and appoints archbishops, bishops, vicars and prefects apostolic who exercise ecclesiastical jurisdiction throughout the world.

The reigning pontiff at the beginning of the decade

1937-46 was Pius XI (*q.v.*), 260th successor to the see of St. Peter.

After Pius XI's death on Feb. 10, 1939, at the age of 82, Eugenio Cardinal Pacelli, secretary of state, was proclaimed pope; he took the name of Pius XII (*q.v.*) and was solemnly crowned on March 12.

Charged with the duty of assisting the pope in the administration of ecclesiastical affairs is the college of cardinals, titular pastors of churches in Rome. Under a discipline prevailing for centuries it is this body which, on the death of a pontiff, designates his successor in the see of Rome and as head of the Catholic church. With its full complement the college of cardinals consists of 70 members—6 cardinal bishops, 50 cardinal priests, who are bishops, and 14 cardinal deacons.

Pope Pius XI, at the secret consistory of Dec. 13, 1937, brought the Sacred college up to one less than the traditional number of 70. On that date he created five cardinals: Archbishop Arthur Hinsley of Westminster, England; Archbishop Pierre Gerlier of Lyons, France; Giuseppe Pizzardo, secretary of extraordinary affairs; Ermengildo Pellegrinetti, apostolic nuncio to Yugoslavia; Adeo-dato Giovanni Piazza, patriarch of Venice, Italy. With these additions, the composition of the Sacred college was 39 Italian and 30 non-Italian members. The 1937 consistory was the last in which cardinals were created until the history-making one in Feb. 1946.

In the interim the Sacred college had dwindled to 38 members.

On Dec. 23, 1945, Pius XII announced the names of 32 prelates to be raised to the cardinalial dignity. The consistory was scheduled for Feb. 18, 1946. At this consistory 28 of the 32 cardinals-designate received the red hat; reasons of health prevented the others from attending. In making the announcement the pope stressed the universal and supranational character of the church. His choice of those to be honoured bespoke this internationalism. Of the 32 new cardinals 4 were Italians and 28 from other countries. For the first time since the time of the Schism of the West, the Italian cardinals were in a minority.

All continents were now represented in the Sacred college.

The prelates designated to be cardinals by Pius XII on Dec. 23, 1945, were: Gregory Peter XV (Agagianian), patriarch of Cilicia of the Armenians; John Joseph Glennon, archbishop of St. Louis, U.S.; Benedetto Aloisi Masella, apostolic nuncio to Brazil; Clemente Micara, apostolic nuncio to Belgium and internuncio to Luxembourg; Adam Stephen Sapieha, archbishop of Cracow, Poland; Edward Mooney, archbishop of Detroit, U.S.; Jules Gerand Saliège, archbishop of Toulouse, France; James Charles McGuigan, archbishop of Toronto, Canada; Samuel Alphonsus Stritch, archbishop of Chicago, U.S.; Agustin Parrado y Garcia, archbishop of Granada, Spain; Emile Roques, archbishop of Rennes, France; Jan de Jong, archbishop of Utrecht, Netherlands; Carlo Carmelo de Vasconcelos Mota, archbishop of São Paulo, Brazil; Petit de Julleville, archbishop of Rouen, France; Norman Gilroy, archbishop of Sydney, Australia; Francis Joseph Spellman, archbishop of New York, U.S.; José Maria Caro Rodriguez, archbishop of Santiago, Chile; Teodosio Clement de Gouveia, archbishop of Lourenço Marques, Mozambique; João de Barros Camara, archbishop of Rio de Janeiro, Brazil; Enrico Pla y Daniel, archbishop of Toledo and primate of Spain; Manuel Arteaga y Betancourt, archbishop of Havana, Cuba; Joseph Frings, archbishop of Cologne, Germany; Juan Gualberto Guevara, archbishop of Lima, Peru; Bernard William Griffin, archbishop of London, England;

Emanuel Arce y Ochotorena, archbishop of Tarragona, Spain; Joseph Mindszenty, archbishop of Esztergom, Hungary; Ernesto Ruffini, archbishop of Palermo, Sicily; Conrad von Preysing, bishop of Berlin, Germany; Clement August von Galen, bishop of Muenster, Germany; Antonio Caggiano, bishop of Rosario, Argentina; Thomas Tien, vicar apostolic of Tsingtao, China; Giuseppe Bruno, secretary of the Sacred Congregation of the Council.

Two of the above died shortly after receiving the red hat. Cardinal Glennon died in Ireland on March 7, while returning to the United States, and Cardinal von Galen died in Germany on March 22, 1946.

Canonizations.—The death of Pius XI and subsequent war conditions somewhat slowed up the processes of canonization and beatification. Nonetheless, a number of persons were raised to sainthood or declared blessed. In 1938 three saints were solemnly proclaimed on Easter Sunday: Andrea Bobola (1591–1658), a Jesuit priest martyred in Russia; Giovanni Leonardi (1541–1609), founder of the Clerks Regular of the Mother of God; and the Spanish lay-brother of the Franciscans, Salvador da Horta (1520–1567). On May 2, 1940, Pope Pius XII canonized Mary Euphrasia Pelletier (1796–1868), foundress of the Sisters of the Good Shepherd and Gemma Galgani (1878–1903), tertiary of the Passionist order. In 1944 the canonization of Margaret of Hungary, daughter of King Bela IV, was announced. On Jan. 11 of the same year approval for the canonization of Mother Frances Xavier Cabrini, (1850–1917) U.S. citizen, was given. Thirty thousand persons packed the Basilica of St. Peter on July 7, 1946, for Mother Cabrini's canonization ceremony, which had been delayed by World War II. Sixteen cardinals and some 70 bishops were present; among the U.S. pilgrims were Archbishop Amleto Cicognani, apostolic delegate to the U.S., and Bishops Gerald P. O'Hara, Charles Greco and Bernard Sheil. Mother Cabrini had been beatified in Nov. 1938.

Beatified just before or during World War II were: Maria Giuseppa Rossella (1811–1880), foundress of the Congregation of the Daughters of Our Lady of Mercy, on Nov. 6, 1938; Maria Domenica Mazzarello (1837–1881), co-foundress of the Daughters of Mary Help of Christians, on Nov. 20, 1938; Rose Philippine Duchesne (1769–1852), who introduced the Society of the Sacred Heart into the U.S., on May 12, 1940. On Dec. 13, 1945, Pope Pius XII signed decrees approving the beatification of Maria Teresa Soubiran and Maria Teresa Veresi, both foundresses of institutes of religious women. The causes for canonization of Louis Grignon de Montfort, and the Jesuit missionaries Bernardino Realini and John de Britto, were also approved. A number of other causes were given attention, but wartime conditions rendered difficult the necessary interchange of documents. Notable among the causes promoted were those of Pope Pius X, who died in 1914, and of Kateri Tekakwitha, Mohawk Indian maiden of colonial days. On Nov. 24, 1946, Pope Pius XII solemnly beatified 29 martyrs who shed their blood for the faith during the Boxer rebellion in 1900; 26 of the martyrs were members of the Franciscan order.

Other Papal Official Acts.—Among the 11 congregations which carry on the executive functions at the Vatican is the Holy Office. It has always occupied a prominent position because of its activities in safeguarding faith and morals. In April 1938 the Holy Office issued a revised edition of the Index of forbidden books. It included all additions made since the previous Index published in 1929. Another revised edition of the Index, bringing the list up to date, was published in 1940. Titles of books currently

condemned continued to appear in the various numbers of *Acta Apostolicae Sedis*, official documentary publication of the Vatican. Some of the works placed on the Index within the decade were *Etudes sur Descartes*, by L. Laberthonniere; *Klosterleben*, by B. Assmus; three books of Pietro Martinetti; eight books of Alfred Loisy; three by Aloisia Piccareta; two German treatises by Raoul France and Gustav Mensching respectively; a New Testament dissertation by O. Lemaire; *Solus ad Solam*, by Gabriele d'Annunzio; *La Grande Sintesi* and *L'Acesi Mistica*, by Pietro Ubaldi; all the works of Alfredo Oriani; *L'enfant prophète Jesus*, by E. Fleg; *Der Christ als Christus*, by Karl Pelz.

Several decrees of the Holy Office attracted wide interest. In 1940 an official decision on the morality of eugenic sterilization was handed down. The practice, whether temporary or permanent, was condemned as unlawful. Also condemned was killing by the state of mental or physical defectives. This latter crime, it will be remembered, was indulged in by the nazis as part of their program for strengthening the race, saving money or carrying out experiments.

On April 1, 1945, the Holy Office issued a decree clarifying the ends of marriage. The decree condemned the opinion that the primary end of marriage is not the generation and education of children. There are, of course, secondary ends to which great importance attaches, but the decree called attention to the fact that confusion of thought and terminology should not be introduced by referring to them as primary.

In Oct. 1946 a decree was issued empowering bishops to designate priests who would be permitted to confirm the dying. The purpose of the decree was to make it possible for all to receive the sacrament of confirmation even though a bishop might not be readily available.

War conditions occasioned the granting of several privileges and the issuing of new instructions. The use of electric light or oils, other than olive oil or beeswax, was permitted for sanctuary lamps in time of emergency. Evening celebration of Mass, with full approval of ecclesiastical authorities, became common in the armed forces of the belligerents. Because of war conditions permission was granted in 1940 to anticipate the midnight Mass on Christmas during the afternoon of Christmas eve. Modifications in the Eucharistic fast were also allowed those engaged in war work, at the discretion of the bishop. In 1943 the Sacred Congregation of the Sacraments broadcast to all countries new instructions for caring for the Blessed Sacrament during war emergencies. Designated laymen were authorized to seek out the Sacred Hosts scattered by bombing. In 1944 the Sacred Penitentiary, the Roman tribunal which dealt with matters of the internal forum and decided cases of conscience, issued two notable decrees. Soldiers in danger of death in battle and civilians in danger during a hostile incursion were granted absolution without previous confession. German bishops were given power to permit priests to reconcile to the church Catholics who had lapsed under nazi persecution. In 1943 through the Sacred Congregation for Extraordinary Ecclesiastical Affairs, the pope granted to bishops all over the world the wartime faculty of dispensing their flocks from the precepts of fast and abstinence. Two days, Ash Wednesday and Good Friday for the Latin rite and equivalent days for Oriental rites, were excepted from the dispensation. The faculty, to be used at the discretion of the ordinaries, was for the duration of the war.

Previous to the war emergency a notable decree was issued by the Sacred Penitentiary on July 22, 1939, to the effect that a plenary indulgence might be imparted over the radio.

The Sacred Penitentiary is but one of three Roman tribunals which handle the judicial matters brought to the attention of the Holy See. The jurisdiction of the Sacred Penitentiary is limited, as was pointed out, to questions of conscience and the internal forum, either sacramental or nonsacramental. Among these is numbered the concession of indulgences and conditions for gaining them. The other two tribunals are Apostolic Signatura, which is the supreme tribunal of the Roman Curia, and the Sacred Roman Rota. To the Rota devolve all contentious cases, requiring judicial procedure with trial proofs, civil as well as criminal (not major ones), which are treated in the Roman Curia. The Rota attracts much attention because of its function of passing final decision on marriage cases. During the decade 1937-46, including the war years, the Rota devoted a considerable portion of its time to such cases. In 1937 decisions were rendered on 78 marriage cases, in 34 of which decrees of nullity were awarded. It was worthy of note that in 21 of these annulments, the petitioners were so poor that they were unable to pay even the ordinary expenses of judicial processes. In 1938 decisions were rendered in 80 marriage cases. Of the 74 appeals made for a declaration of nullity, the decree of annulment was granted to 30. In 1939 the decree of nullity was issued in only 19 cases; marriage was held to be valid in 46 cases. That year 25 petitions sought annulment because of lack of consent; only three decrees of nullity were granted for this reason. In 1940 of the 56 applications for decree of nullity, 39 were rejected; 14 were granted and the marriage declared null; two dispensations were granted of marriage contracted but not consummated; one was held void because of procedure. During the judicial year of 1942 the Rota heard 87 marriage cases. Of the total, 29 decrees of nullity were granted. While the number of marriage cases referred to the Rota from the lower courts varied somewhat, the ratio of decisions remained about the same. Normally, considerably less than half the applications for decree of nullity had been granted, and the remainder of the marriages upheld. The same proportion was discernible during the decade. In the majority of cases, annulments were granted for reasons readily ascertainable, such as impotence, insanity, force and fear; few were for defect of consent.

Because of the war, a memorable departure from usual procedure in matrimonial cases took place. On July 30, 1942, a papal rescript authorized the apostolic delegate to the United States to designate matrimonial courts to hear cases usually delegated to the Sacred Roman Rota.

Papal Pronouncements.—In the prewar and war years the thinking of the church continued to be clarified through papal encyclicals. The drive for cleaner motion pictures, which had gained momentum in the early 1930s in the United States, received papal backing in the encyclical letter *Vigilanti cura*, on clean motion pictures, issued in 1936 by Pius XI. The following year, in the encyclical *Firmissimam constantiam*, the Holy Father made manifest his anxiety about the state of the church in Mexico, where it was under many restrictions and was experiencing what at the time amounted to persecution. The same year Pius XI issued an encyclical on the Rosary. But the most outstanding documents of 1937 were the two encyclicals on naziism and communism. Both systems were uncompromis-

ingly condemned. The encyclical on naziism, known by its German title *Mit brennender sorge*, rejected racism as a theory and racial discrimination as a practice. Nazi denial of religious freedom was condemned, together with the totalitarian inhumanity of the nazi leaders. In the encyclical *Divini Redemptoris*, Pope Pius XI developed his teaching on contemporary social problems, showing that communist theory is opposed to Christian principles of social organization. Not only does it deny private property as an institution, but it distorts man's spiritual nature and leads to atheistic totalitarianism. While rejecting communism, the Holy Father pointed out patent abuses of the capitalistic system, emphasizing the duty of the state and of society in general to take effective steps to guarantee social justice to all.

One of the first acts of the new pope, Pius XII, was to issue an encyclical letter on the unity of human society (*Summi pontificatus* was the title). It appeared on Oct. 20, 1939, a short time after the outbreak of World War II. In it the Holy Father drew attention to two "pernicious errors," popularly known as racism and totalitarianism. The first of these, he said, denies the unity and solidarity of the human race; the other attributes to the state complete supremacy in all matters, including religion and morals. These errors, the pope maintained, imply a denial of the norm of human morality and destroy the true function of the family and the state.

Attention was focused on the progress and problems of the U.S. church in the encyclical *Sertum laetitiae* issued by Pius XII on Nov. 1, 1939. Praising U.S. Catholics for their generosity and devotion, the letter pointed out that forthright steps must be taken to correct social abuses and injustice in the United States. The letter praised the efforts of those endeavouring to apply the principles taught in the encyclicals of Pius XI on social questions. In 1940 there appeared an encyclical on the missions, and in 1943 one on the Mystical Body of Christ, clarifying some doctrinal points and warning against a false mysticism. In 1943 there was issued an encyclical letter on biblical studies, entitled *Divino afflante Spiritu*. In it the pope stressed the need and desirability of scripture study, emphasizing the fact that there was still much room for exegesis and research in this field.

Many of the statements issuing from the Vatican during the war years dealt with the problems of peace and reconstruction. Outstanding was the 1939 Christmas address of the pope, in which he laid down five conditions for a just and durable peace. These five points later came to be known as the Pope's Peace plan. The other allocutions of Pius XII on Christmas Eve each year during the war in some way touched on peace. In 1942, for example, he effectively summarized the moral principles governing the internal order of states and peoples, particularly as they were related to international order. In the 1944 Christmas address Pius XII developed the concept of democracy, stressing the rights of citizens, the nature of civil authority and the need of genuine democracy for the preservation of peace. The 1945 Christmas allocation treated of the internationalism, or rather the supranationalism, of the church. This subject was especially apt inasmuch as on that occasion the pope indicated the internationalizing of the college of cardinals through selection of prelates from many countries to receive the red hat.

Thirty-two new cardinals were created at a consistory in the Vatican on Feb. 18, 1946, placing Italians in the minority in the Sacred College of Cardinals for the first time. Cardinal Stritch of Chicago is shown receiving his red hat as he knelt before Pope Pius XII in St. Peter's cathedral

Two other outstanding addresses of Pius XII were the radio address of June 1, 1941, in which he forcefully summarized the social teachings of Leo XIII, Pius XI and his own earlier statements and the address of 1945 on the duties of women in social and political life. The former stressed the achievement of economic democracy and social justice as the necessary condition of peace; the latter pointed out the role which must be played by women in the reconstructing of modern society.

Church and the War.—Conflict with the government of the third German reich was the lot of the church almost from the first days of the Hitler regime. Although approximately one-third of Germany was Catholic, the nazis had repeatedly violated the rights of the church guaranteed in the concordat with the Vatican, ratified Sept. 10, 1933. By 1937 the conflict had become bitter. In February of that year Cardinal Faulhaber openly accused the nazis of persecution of religion, and on March 14, 1937, the encyclical of Pius XI condemning nazi racist doctrines was released. The nazis refused to discuss the problem with the papal nuncio and on May 1, Hitler warned that all churches opposing the philosophy of national socialism would be suppressed.

In 1938 the nazi attack upon Catholicism was intensified. Vilification of priests and religion was common in the press and in public. Mobs attacked the residence of Michael Cardinal von Faulhaber, and Bishop Sproll of Rottenburg was expelled from his diocese. The religious press was suppressed. So, too, were Catholic youth organizations. Educational establishments were systematically destroyed through the technique of preventing or discouraging youth from attending them. In Oct. 1938, Pope Pius XI assailed the vicious misrepresentations that the German and Austrian church was engaging itself in political affairs. In March 1938 the persecution of the Austrian church began. Under promise that the rights of religion would be respected, the Austrian hierarchy accepted the union of Austria with the reich. Almost at once the same persecution experienced in Germany was extended to Austria. Because of his protests, Theodore Cardinal Innitzer was attacked in his home in Oct. 1938, and put under protective guard. Nazi decrees on marriage, ethical matters and education widened the gap between the church and the state in both Germany and Austria.

In the months immediately preceding the outbreak of war the Holy See did everything within its power to avert the catastrophe. Pius XII seized every opportunity to issue appeals. He did not wish to alienate the Catholics of any of the nations involved, although his insistence that justice be done made it quite clear that the actions of aggressors were not approved. Through diplomatic channels the pope attempted to promote conferences among the powers, but without success. The pope made it clear that he did not wish to involve the Holy See in political or territorial disputes.

When Poland was overrun by the nazis and soviets, the Holy See expressed deep sympathy with the Polish people and condemned the attack upon that nation. On Oct. 7, 1939, the Vatican recognized the Polish government set up in Paris, France.

In Italy, meanwhile, all was not peace. Technically the Italian government had lived up to most of the provisions of the concordat entered into with the Vatican in 1929. Actually, extreme fascist elements had conducted an anticlerical and antipapal campaign which grew in intensity with the years. In 1940 the anticlerical aspects of fascism

became more manifest. Matters became more complicated because of the pro-fascist leanings of some of the clergy in the years before the war. As the excesses of fascism became more apparent, however, the gulf between the church and the fascist leadership widened.

In 1940 every effort was made in Germany and Austria to win the allegiance of younger clerics to the nazi cause. The report, later proved false, was circulated that the bishops, after their Fulda meeting, would issue a statement favourable to the nazis, and that diplomatic agreements had been reached between Germany and the Holy See. In Poland Augustus Cardinal Hlond declared that the country was enduring a "wave of unparalleled atrocities and cruelties." Subsequently a nazi decree ordered that baptism could be administered only by German priests, and nazi governors in Poland issued orders that hymns and prayers referring to Poland were prohibited. Church property was confiscated as occasion arose, and priests were imprisoned or executed.

Belgium predominantly Catholic, Netherlands 50% Catholic and Luxembourg nearly 90% Catholic, suffered in loss of church property and through nazi antireligious propaganda. On May 11, 1940, Pius XII pledged the moral support of the Holy See to these countries, condoling with their rulers on the nazi invasion. The bishops of Netherlands, in 1941, issued three strong pastoral letters: the first warned against Catholic participation in nazi or communism movements; the second denounced nazi usurpation or suppression of Catholic organizations; the third refused the sacraments to members of nazi groups. Similar protests were made by the Belgian hierarchy.

Belgian resistance grew among Catholics. In a pastoral dated Feb. 1, 1942, Joseph Ernest Cardinal van Roey of Malines refused to accept nazi domination of religion in Belgium. He also forbade holy communion to Flemish nazis wearing uniforms in church. The Benedictine abbeys of St. André, Mont César and Maredsous were confiscated by the nazis. In 1942 Father Weechmans was sentenced to eight years hard labour for publishing the Catholic journal *La Belge*. In Netherlands the Catholic papers were progressively suppressed when they refused to conform to nazi demands.

In Germany, as the war went on, hostility between the government and the hierarchy grew. In 1941 a pastoral of the German bishops cited four major protests: suppression of Catholic publications, disbanding of religious institutes and convents, closing of Catholic schools and prohibition against religious teaching in those remaining open, nazi propaganda seeking Catholic apostasy. Bishop (later Cardinal) von Galen of Muenster, in a series of sermons, denounced the methods of the gestapo against Catholics, as did Bishop Bornewasser of Trier. Archbishop Conrad Groeber of Freiburg declared that the war had increased the persecution of the church in Germany. In German-occupied countries the same situation was manifest. Clergy were arrested for saying anything against the invaders, and institutions were closed. Such was the case in Yugoslavia and the Balkans generally. On March 21, 1943, the Slovakian bishops denounced a nazi law forbidding the baptism of Jews. In Lithuania the bishops accused the nazis of violating their promises to respect religion. To make perfectly clear the position of the Holy See, the Vatican radio in 1943 stated categorically that wartime creation of new states would not be recognized. At the same time another broadcast condemned the atrocities of the Japanese.

The wartime situation in France did not present a clear-cut picture. Some 15,000 priests had been mobilized in the

French army as soldiers or officers; many were killed and others taken prisoner. The difficulty of caring for the faithful's religious needs was greatly increased under the Nazi occupation. Further complications arose as a result of the Vichy government's desire to aid religion; on Sept. 3, 1940, the antireligious laws of 1904 were repealed. Despite their dislike of the Nazis, a certain number of French Catholics felt sympathetic to the Vichy regime because of its abrogation of antireligious laws. Other Catholics could see no point in giving even partial approval to those whom they regarded as collaborators. The latter group, numbering many priests, were especially active in the resistance. A number of the French clergy distinguished themselves by opposing the Nazis at the risk of their lives or by carrying out their ministry under dangerous conditions; a number died in Dachau. In this way respect was won for the Catholic church; it continued into the postwar period. Another effect of the experiences of the war years was a strengthening of religious life among the people.

During the occupation years French Catholic journals opposing collaboration were suppressed by the Nazis, as were papal communications. French prisoners of war in Germany for the first two years after the fall of France were unable to receive holy communion. To combat anti-Semitism, French archbishops and bishops in pastorals and sermons condemned the barbaric treatment of Jews under the Nazi occupation.

With the progress of the war the Nazis grew more daring in their assaults upon religion. On Jan. 1, 1942, Dr. Alfred Rosenberg released a 30-point program for a Nazi national church. On March 22 of the same year the German bishops, in a joint pastoral, cited their protests against the Nazi program, charging the Nazis with wishing to destroy Christianity. At about the same time Cardinal Faulhaber denounced insults to the papacy, and Bishops von Galen and Bornwasser denounced a German government order interning priests in concentration camps. At the Nuremberg trials after World War II it was brought out that the Nazis had planned the complete destruction of the church once the war was won.

Outside the Nazi-occupied countries the hierarchy of the church made clear its position on the Nazi inhumanity. On Oct. 30, 1942, the hierarchy of Brazil condemned totalitarianism and urged all Catholics to defend their country in a just war in defense of Christian civilization. In a statement issued Nov. 14, 1942, the hierarchy of the United States reaffirmed their earlier disapproval of Nazism by declaring there could be no compromise with the axis. In the same year three Italian bishops protested against persecution of Slovenes by Italian authorities. In England the bishops kept urging a peace based on the announced papal principles, recognizing at the same time that no compromise with the axis powers was possible. Cardinal Hinsley especially stressed the fact that peace of a lasting character was possible only if moral principles were adhered to by large numbers of the people. Accordingly he initiated a movement, called *Sword of the Spirit*, which sought to unite all Christians in the defense of Christianity against the aggressive paganism of the totalitarian ideologies.

At the height of the war in 1943 the church suffered heavily from the conflict which had spread to all Europe and much of the Pacific. In Germany the Franciscan order found that 2,943 of its members had been conscripted into the German army as combatants; and during the year 1,200 German priests and members of religious orders were known to have been interned in concentration camps. All orders and the diocesan clergy were affected so that proper

spiritual ministrations to the people became progressively more difficult. In Belgium Canon Cardijn, labour leader, was imprisoned by the Nazis; Abbe Cordonnier was executed by the German authorities for aiding British airmen; Mgr. van Wayenbergh, rector of Louvain university, was sentenced to imprisonment. The bishop of Namur excommunicated the Rexist leader Léon Degrelle consequent to these attacks upon the church and human rights.

In the United States, chiefly through War Relief Services—National Catholic Welfare conference, Catholics contributed to relief drives. In 1943, 23 of the Catholic hierarchy joined with Protestant and Jewish leaders in signing a seven-point declaration on world peace. Widespread efforts were made, through churches and church organizations, to acquaint the people with the peace program and to prepare them for the formation of a postwar international organization. These efforts were continued up to the San Francisco conference of the United Nations in the spring of 1945. Shortly before the conference the Catholic hierarchy, simultaneously with other religious leaders, made clear the moral principles on which such an organization should be founded.

Spread of the war in the Pacific after Dec. 7, 1941, threatened the future of the church in that region. Japan had for some time recognized the legality of the church, and did not change its basic attitude during the war. Fortunately, in line with Japanese policy, the Vatican had progressively substituted native Japanese bishops for foreign prelates. Hence, when the war came little difficulty was experienced on that score. Apparently most Japanese Catholics saw no difficulty in fighting for their country. The church in Japan suffered a great loss, however, when Nagasaki and Hiroshima were wiped out by the atomic bombs. The church had become particularly strong in these cities. In other cities bombing damaged or destroyed churches just as in Europe.

Military operations did considerable harm to missions in the Pacific theatre. Chapels were destroyed and native peoples displaced. In the Philippines, chiefly because of the great loyalty of Filipinos to the United States, the church suffered heavily; the War Damages commission subsequently estimated loss of church and church-connected property at \$125,000,000. About half the churches in the islands were destroyed or in such a condition as to need major repairs. The economic plight of the people added to the difficulties of restoration of churches, institutions and schools. During the war U.S. missionaries who escaped internment were active with resistance groups. When the Japanese realized that the Philippines were lost, they resorted to wholesale destruction. It was at this time that several scores of foreign priests and religious were slain along with loyal Filipinos. Earlier in the war the Japanese had interned a number of priests and religious; some of them were transferred to Japan. Throughout the war supervision of religious affairs by military authorities was very strict. The same condition prevailed in other missionary areas, notably China. Several hundred missionaries were repatriated, and others were interned for the duration of the war.

As the war drew to an end, the antireligious nature of Nazism became even more apparent. On Aug. 19, 1943, the German bishops at Fulda accused the Nazis of open religious persecution. Bishop Dietz of Fulda asserted that beneath the Nazi doctrines were pantheistic ideas. Bishop (later Cardinal) Konrad von Preysing of Berlin vigorously denounced the Nazi attack upon human rights. Cardinal

Justin Seređi, primate of Hungary and archbishop of Esztergom, condemned the master race propagandists as tools of Satan.

When the nazis occupied Italy, the position of the church became precarious. In the centre and north of Italy priests who condemned terror and pillage were seized by the gestapo. The monks of the famous Benedictine abbey of Monte Cassino, founded by St. Benedict himself, were ordered by the nazis to leave their abbey and seek refuge in Rome. Famous treasures, both of the abbey and others sent for safekeeping from various parts of Italy, were seized and sent to Germany. The abbey was later used by the German troops as an observation post, and during the Allied drive through Italy it was destroyed by bombing. In the north of Italy ten rectors of Catholic universities were dismissed from their posts by the nazis. Seven members of the Salesian order were executed by the Germans during 1944. Throughout Italy churches were destroyed in the military engagements. The poverty of the people and their complete exhaustion made reconstruction a slow and difficult task.

The last year of the war witnessed bitter conflict between the church and the German and puppet governments. In the Netherlands, in retaliation for the pastorals condemning naziism and encouraging noncollaboration, clergy who read the letters from their pulpits were arrested. In Hungary Cardinal Justin Seređi was placed under close surveillance, and the Hungarian puppet government banned Catholic publications. Cardinal Hlond, primate of Poland, was arrested at Aachen by the gestapo. Later, when released at Paderborn on April 1, 1945, by the U.S. 9th army, he found that approximately 2,000 of the Polish clergy, including several bishops, had been executed or missing. In Yugoslavia it finally became known that during the war two-thirds of the hierarchy had died, been imprisoned or executed. At least several hundred priests were known to have perished in the Yugoslavian fighting during the war.

Total war damage to the Catholic churches of Europe was estimated at \$6,000,000,000, exclusive of schools and other religious buildings. Some 12,000 Catholic churches in the reich were destroyed or severely damaged. In Italy 65 churches of historic and artistic value were in ruins, and in London 55 churches were wrecked by flying bombs. The two Catholic universities to suffer most during the war were those of Nijmegen, Netherlands, and Louvain, Belgium.

In the Ukraine systematic persecution by the soviets finally succeeded in bringing the Ukrainian Catholic church under the domination of Moscow. An uncanonical synod, unattended by the hierarchy, declared the union with Rome, dating from 1596, to be abrogated as of March 8, 1946. Union with Moscow was forced upon Ukrainian Catholics, and the churches of priests who would not submit were forceably taken over by soviet emissaries. In Jan. 1946 Pope Pius XII, in the encyclical *Orientalis omnes ecclesias*, deplored the persecution of the Ukrainian church. Similar conditions existed in other Slavic countries. The war conditions had made possible the repression of Roman Catholicism among the Slav peoples by the Russians, who substituted the politically controlled Moscow patriarchate as the supreme religious authority.

At the end of World War II there was considerable rejoicing among Catholics in Europe generally. On Dec. 1, 1945, Archbishop Groeber of Freiburg, Germany, said catastrophe would have befallen Europe had the nazis won. The French bishops made an appeal for national union in

a spirit of reconciliation. When the Allies entered Rome the celebration was extensive. On June 11, 1944, about 10,000 officers and men attended a thanksgiving Mass in the cathedral of St. Mary of the Angels in Rome, and 15,000 Allied troops were present at the midnight Mass celebrated by the pope in St. Peter's. Immediately after the German armistice Cardinal Faulhaber led a Corpus Christi procession through bomb-shattered Munich, and on Christmas, 1945, curfew regulations were lifted to permit celebration of midnight Mass in Germany for the first time since 1939. Throughout the world the end of World War II was marked by thanksgiving services in the churches.

Population and Statistics.—Only estimates were available as to the Catholic population of the world. Accurate figures were lacking, as was also the case with other world religious groups. Most estimates placed the Catholic world population in 1946 at 400,000,000 or thereabouts. One set of statistics gave the Catholic population of various continents as follows: Europe 203,944,000; Asia 9,213,413; Africa 6,866,000; North America 47,056,724; South America 60,836,000; Oceania 10,468,000. These figures placed the total in 1946 about 60,000,000 fewer than 400,000,000, but they did not take sufficiently into consideration the growth of population and the number of baptized Catholics who might not be practising their religion. There were estimated to be 128,000,000 orthodox and schismatic Catholics in the world; and 135,000,000 Protestants. This made the total number of Christians about 601,000,000, of whom well over half were in union with Rome. Non-Christians in the world totalled at least 1,500,000,000, of whom 15,000,000 were Jews; 220,000,000 Mohammedans; and 1,319,000,000 members of other religions.

During the decade there were two elections to patriarchates. In 1937 Gregory Peter XV Agagianian became patriarch in the Armenian rite of Cilicia, Turkey. In 1940 Giuseppe da Costa Nunes became patriarch of the East Indies, Latin rite, with headquarters in Goa, India. The patriarchate of the West Indies, with its residence in Madrid, remained vacant. The total number of patriarchates, exclusive of that of all the west, which belongs to the reigning pope, was fourteen. There were four major patriarchates in the eastern church: the Coptic patriarchate of Alexandria, and Syrian, Maronite and Melchite patriarchates of Antioch in Syria. There were two minor eastern patriarchates: the Chaldean patriarchate of Babylon in Iraq, and the Armenian patriarchate of Cilicia, Turkey. The Latin patriarchates of Constantinople, Alexandria and Antioch remained merely titular. Minor Latin patriarchates in the west—Venice, Lisbon, the East Indies and the West Indies—were also merely titular.

In 1945 the Vatican maintained diplomatic relations with 36 countries. There were 26 nuncios, 2 internuncios, 6 chargés d'affaires. The pope appointed Bishop Joseph P. Hurley of St. Augustine, Fla., to act as regent ad interim of the apostolic nunciature in Belgrade, Yugoslavia. In addition the Vatican had 22 apostolic delegates, or representatives without diplomatic accreditation, in as many countries or territories. The representative in the United States was an apostolic delegate and did not enjoy diplomatic status. Pres. Franklin D. Roosevelt, at the beginning of World War II, appointed Myron C. Taylor as his personal representative at the Vatican, with the rank of ambassador but without diplomatic status. In 1939 there were accredited to the Holy See 13 ambassadors and 27 ministers and envoys extraordinary. In that year diplomatic relations were resumed between Lithuania and the Vatican, after having lapsed in 1932. Representatives were exchanged also with Uruguay for the first time since 1898.

Nuns entering the order of the Missionary Sisters of the Sacred Heart in Italy. The order was founded by Mother Frances Xavier Cabrini, who was canonized by Pope Pius XII at Rome on July 7, 1946, the first U.S. citizen to be so designated

In 1939 there were 39 papal nuncios and internuncios, accredited to as many nations, and 23 apostolic delegates.

There were 1,695 ecclesiastical jurisdictions in 1938 throughout the world. Of these 14 were patriarchates, seven of them titular; 1,194 archbishoprics and bishoprics; 487 vicariates and prefectures apostolic. In the United States there were 19 archbishoprics, three of them governed by cardinals, 94 bishoprics and two vicariates. In England and Wales there were four archbishoprics, including the cardinalitial see, and 14 bishoprics. Scotland had two archdioceses and four dioceses. Ireland had four archdioceses and 25 dioceses. Canada had 12 archbishoprics, 28 bishoprics and 7 vicariates.

In both Ireland and Canada one of the archbishops was a cardinal.

In 1941 there were 1,210 archbishoprics and bishoprics, 512 vicariates and prefectures apostolic and other prelates throughout the world. In that year the number of titular archbishops and bishops totalled 779. These titular prelates were without territorial jurisdiction of their own and were engaged in assisting residential prelates or in filling Vatican posts. In 1942 the number of residential sees, including archbishoprics and bishoprics, was 1,223. Since he became pope, Pius XII had created 72 new ecclesiastical jurisdictions. In that year ecclesiastical jurisdictions in the United States numbered 117. There were 2 cardinals, 20 archbishops, 97 bishops and vicars apostolic. The clergy numbered 36,580—23,818 diocesan priests and 12,762 regular. The total number of parishes and missions in the United States in 1942 was 18,985.

In 1943 the number of residential sees throughout the Catholic church was 1,226. In the United States ecclesiastical jurisdictions numbered 118. Catholics in the United States numbered 22,945,247. There were 24,031 diocesan

priests and 12,939 regular priests. Parishes and missions numbered 18,976; high schools 1,522; parochial schools 7,647. Seminaries were reduced by ten, to 193.

In 1946 the number of Catholics in the United States was estimated at 24,402,124, out of a total population of 133,053,845. There were 5 cardinals, 18 archbishops, 135 bishops, 28 abbots, 38,980 priests. Archbishoprics numbered 22; bishoprics and other jurisdictions 100. In Canada and Newfoundland there were 13 archdioceses; 34 dioceses; 9 vicariates apostolic and other jurisdictions. Of a total population of 11,795,000, Catholics were estimated as numbering 5,000,000. In England and Wales there were 4 archdioceses, 14 dioceses. The Catholic population of England and Wales was somewhat over 2,400,000. In Scotland, with a Catholic population of 615,000, there were two archdioceses and four dioceses. The Catholic population of Ireland was given as 2,773,920, out of a total of 2,951,000. In Northern Ireland the Catholics numbered 455,352, the total population being 1,303,000. Ecclesiastical jurisdictions remained the same: 4 archbishoprics and 25 bishoprics.

Year-by-Year Developments.—In 1937 every see was filled in the United States for the first time in many years. Three dioceses were raised to archdioceses, and four new dioceses were created. In the Vatican diplomatic service a *modus vivendi*, after a lapse of relations for 63 years, was arrived at by the Holy See and Ecuador. The *modus vivendi* with Czechoslovakia, executed in 1928, began to go into effect. At the coronation of King George VI, the pope was represented by Archbishop (later Cardinal) Pizzardo. Semi-official relations were entered into with the Nationalist government in Spain. Dennis Cardinal Dougherty of Philadelphia, Pa., was sent as papal legate to China and Japan. In loyalist Spain obstruction of the practice of religion was common, and on July 1, the Spanish hierarchy sent a joint letter to the bishops of the world protesting against the loyalist government. Pope Pius XI issued his encyclicals

against communism and nazism. On Feb. 3, 1937, the 33rd International Eucharistic congress was opened in Manila, P.I., with Cardinal Dougherty acting as papal legate. India celebrated the 50th anniversary of the establishment of its hierarchy. During the half century the Catholic population had increased from 1,660,000 to 4,000,000.

Seven cardinals died in 1938. In the United States two dioceses were raised to archdioceses and four new dioceses were created. During the last week of May 1938, 19 cardinals, about 300 bishops and archbishops and upward of 400,000 clerical and lay pilgrims from 40 nations assembled in Budapest, Hungary, for the 34th Eucharistic congress. In Canada the first national Eucharistic congress was held at Quebec, and in the United States the eighth national Eucharistic congress was held at New Orleans, La. The 150th anniversary of the first Catholic settlement in Australia was celebrated, and the 100th anniversary of the founding of the church in New Zealand. At Montezuma seminary in New Mexico the first ordination of Mexican priests took place. The seminary had been established by the American hierarchy because of disturbed conditions in the Mexican church.

Pope Pius XI died on Feb. 10, 1939. On March 2, Cardinal Pacelli, papal secretary of state, was chosen as his successor, taking the name of Pius XII. During the year four cardinals died. In the United States Washington was designated as an archdiocese, to be administered by the archbishop of Baltimore. Gallup, N.M., was constituted a diocese. Archbishop Spellman was installed in the see of New York, N.Y.; he also was designated ordinary of the armed forces. Archbishop Stritch succeeded Cardinal Mundelein in the see of Chicago, Ill. Pres. Roosevelt sent Myron C. Taylor to the Vatican as his personal representative. On Christmas Eve the pope announced his five-point peace program. The encyclical *Sertum laetitiae* was sent to U.S. bishops on Nov. 1. On Oct. 20, 1939, the Holy Father had issued his first encyclical to the Universal church on the unity of the human race.

Two more cardinals died during 1940; no vacancies were filled. In Spain the new government pledged its allegiance to the Holy See. The pope addressed an encyclical to Portugal on its eighth centenary as a nation. On May 7, 1940, a concordat was concluded with the Vatican.

In 1941 the ninth national U.S. Eucharistic congress was held in St. Paul, Minn., in June with Cardinal Dougherty as papal legate. Denver, Colo., was made an archdiocese, and Pueblo, Colo., and Honolulu were created dioceses. After the attack on Pearl Harbor the U.S. hierarchy pledged full co-operation in the war effort. In April 1941 Roderick Cardinal Villeneuve of Quebec appealed for unity in the war effort of Canada. In Latin America Catholic authorities showed themselves agreeable to the establishment of better relations with the United States. In Mexico the church was heartened by the tolerant attitude of Pres. Avila Camacho. In Brazil the Catholic university of Brazil, authorized in 1939 by a plenary council, was opened.

In 1942 the College of cardinals was reduced to 49 after three more deaths. By July Catholic chaplains in the armed forces of the United States numbered 1,101. The Bishops War Emergency Relief committee distributed \$1,322,493 for relief of prisoners of war and war sufferers. In Great Britain the Bournemouth Union of Christian Thought, representing Catholics, Protestants and Jews, presented an irreducible minimum on which religious people could support any political party. In the United

States Bishop Joseph Raphael Crimont, vicar apostolic of Alaska, celebrated his 50th anniversary as a bishop.

During 1943 six more cardinals died, and no vacancies were filled. Bishop Bernard Griffin, auxiliary of Birmingham, was named archbishop of Westminster, as successor to Cardinal Hinsley. On April 19 Vatican City began a weekly broadcast in Russian to prisoners of war and persons in occupied territory. Archbishop Spellman, ordinary of the U.S. armed forces, visited the soldiers on all fronts. Bishop Johannes Gunnarsson, S.M.M., was consecrated bishop for Iceland on July 7. Archbishop Thomas J. Walsh of Newark celebrated his episcopal silver jubilee.

Two cardinals died during 1944, bringing the membership of the Sacred college down to 41. One of them was Cardinal William Henry O'Connell of Boston, Mass. Before D-day, 95% of the Catholic troops in Britain received holy communion. In China Mgr. Zanin, Vatican representative, was imprisoned by the Japanese at Shantung, and Italian missionary priests were interned. On June 18 Bishop Picaud of Bayeux celebrated a *Te Deum* in his cathedral for the deliverance of France. In Germany it became known that one-fourth of the Catholic priests and seminarians called to the army were casualties. Mgr. Marella, apostolic delegate to Japan, visited Allied prisoners in the Japanese concentration camps. In Yugoslavia 80 Catholic priests were reported killed in Croatia. In the United States four new vicars were appointed to the military ordinariate in 1945, making the total 21. In Vatican City the *Osservatore Romano*, semi-official organ of the Vatican, appealed to the belligerents to relax the blockade. In Britain Bishop Bernard Griffin was enthroned as archbishop of Westminster on Jan. 18. The pope designated the states of Ohio and Indiana as ecclesiastical provinces, with metropolitan sees at Cincinnati and Indianapolis respectively. Two new dioceses were created: Lafayette, Ind., and Evansville, Ind. Bishop Richard J. Cushing, formerly auxiliary of Boston, was named successor of Cardinal O'Connell in that see. Pres. Roosevelt appointed Archbishop Spellman to the Protection and Salvage of Artistic and Historic Monuments in War Areas. While in Rome Archbishop Spellman celebrated a requiem mass for former Gov. Alfred E. Smith. Mgr. Walter S. Carroll was appointed by the pope as chairman of the Vatican commission for regulating religious, political and social affairs with the Allies.

In 1945 the death of three cardinals reduced the total number in the Sacred college to 38. Two of the cardinals who died were noted for their opposition to the nazis during the occupation: Cardinal Adolph Bertram, archbishop of Breslau, Germany, and Cardinal Seredi, archbishop of Strigonia and primate of Hungary. On Dec. 23, 1945, the pope announced a consistory and designated 32 prelates who would receive the red hat. In his Christmas address the Holy Father stressed the universal and supranational nature of the church. It was announced that of the 172 U.S. chaplains who had died during the war, 67 were Catholic priests. Commenting on the situation in Yugoslavia, *Osservatore Romano* stated that three obstacles stood in the way of social and religious peace in Yugoslavia: orthodox church opposition to a concordat with the Vatican, political and cultural divergences between Croats and Slovenes and the Serbs and the favouring of communism by Marshal Tito. On the death of Pres. Roosevelt memorial services were held in many Catholic churches throughout the world, including the American church in Rome. In a joint statement the British hierarchy proposed an eight-point program to the United Nations for the preservation of peace. The centenary of John

Henry Cardinal Newman's conversion was solemnly celebrated, with 500 delegates from 16 countries present. About 100,000 Catholics of Mexico and other American countries gathered at Guadalupe, Mexico, to participate in the golden jubilee celebration of the crowning of the Blessed Virgin of Guadalupe. On July 6, 1945, the Vatican announced the excommunication of Most Rev. Don Carlos Duarte da Costa, bishop of Maura in São Paulo state, Brazil, for preaching revolutionary doctrines. In November classes were resumed in most of the major theological schools in Rome; the American and British colleges still remained closed. In China Generalissimo Chiang Kai-shek welcomed back Bishop O'Gara. In the United States the diocese of Salina was established and the Concordia see was transferred to it. Omaha, Neb., was raised to an archdiocese, and the new diocese of Steubenville, O., was established.

Bishop Apollinaris Baumgartner, O.F.M.Cap., was consecrated and became vicar apostolic of Guam. Louis F. Budenz, managing editor of the *Daily Worker*, communist paper, returned to the church and joined the faculty of Notre Dame university.

In St. Louis, Mo., the Saint Vincent de Paul society celebrated its centenary.

In 1946 at the February consistory 28 new cardinals received the red hat; the other four received it privately. In the United States the diocese of Madison, Wis., was created. Sen. Robert F. Wagner embraced the Catholic faith. In January Pres. Harry S. Truman conferred the Congressional Medal of Honour on Father Joseph T. O'Callahan, S.J., of the navy; he was the first chaplain in the nation's history to receive this award. Shortly after the February consistory two of the newly created cardinals died. The Holy Father commemorated the 350th anniversary of the Ukrainian church's reunion with Rome by the encyclical *Orientalis omnes ecclesias*. Eugene Cardinal Tisserant, secretary of the Congregation for the Oriental Church, declared that the Catholic church east of the Curzon line was being systematically suppressed by the soviet. In April 1946 the pope made a plea to the world to combat famine in war-ravished lands without discrimination. Bishop D'Alton of Meath was named primate of all Ireland. In May Cardinal Griffin made a visit to the United States. The pope announced that China was raised from missionary status and now had its own hierarchy. The major religious orders elected new superior generals to replace those who died during the war: the Capuchins named Fr. Clement Neubauer, native of Milwaukee, Wis., the Society of Mary named Father Sylvester P. Juergens, provincial of the St. Louis province; the Jesuits selected Fr. John Baptist Janssens, a Belgian; the Dominicans chose Fr. Emmanuel Suarez. Two superior generals died: Most Rev. Valentine Schaaf, of the Friars Minor, and Very Rev. Henry I. Stark, who had just gone out of office as superior general of the Paulists. In Yugoslavia Archbishop Stepinac was put on trial and sentenced to prison by the Tito government; the Vatican announced that those who participated in the trial were excommunicated. Protests came from around the world to the Yugoslav government. The 300th anniversary of the death of the North American Jesuit Martyrs was celebrated in the United States, the pope making a special radio address on the occasion. In Oct. 1946 the third of the cardinals created at the February consistory died; he was Cardinal Augustin Parrado y Garcia, archbishop of Granada, Spain. Bishop Raymond A. Lane was elected Maryknoll's superior general in August.

Bishop Martin O'Connor, auxiliary of Wilkes-Barre, Pa., was appointed rector of the North American college

in Rome.

Catholic Awards in the U.S.—The Laetare medal award to outstanding Catholic laymen, on Laetere Sunday (fourth Sunday of Lent) was established by the university of Notre Dame in 1883. Within the decade 1937-46 the recipients were as follows: 1936 Richard Reid, editor; 1937 Jeremiah D. M. Ford, professor; 1938 Dr. Irvin Abell, physician; 1939 Josephine Brownson, founder of Catholic Instruction League; 1940 Hugh A. Drum, Lt. Gen. U.S. army; 1941 William Thomas Walsh, author; 1942 Helen C. White, author; 1943 Thomas F. Woodlock, writer and apologist; 1944 Anne O'Hare McCormick, journalist; 1945 G. Howland Shaw, sociologist and diplomat; 1946 Carlton J. H. Hayes, diplomat and author.

The Hoey awards, granted each year on the Feast of Christ the King to two Catholic laymen outstanding in the work of interracial justice, went to: 1942 Frank A. Hall, director of the National Catholic Welfare conference (N.C.W.C.) news service, and Edward LaSalle, president of Catholic Interracial council of Kansas City, Kans.; 1943 Philip Murray, president of Congress of Industrial Organizations, and Ralph H. Metcalfe, Negro field consultant of United Service Organizations; 1944 Mrs. Edward V. Morrell, promoter of educational work for Negroes, and John L. Yancey, civic leader; 1945 Paul D. Williams, co-founder of Catholic Committee of the South, and Richmond Barthe, sculptor; 1946 Richard Reid, editor, and Charles L. Rawlings, president of Detroit Catholic Interracial council.

The Catholic Action Medal, awarded annually by St. Bonaventure college to a layman outstanding in Catholic action, went to: 1936 Hon. Joseph Scott, lawyer and lecturer; 1937 Patrick Scanlan, editor; 1938 George P. Gillespie, leader in St. Vincent de Paul Society; 1939 William F. Montavon, director of legal department, N.C.W.C.; 1940 John J. Craig, director of Catholic Evidence Conference; 1941 John S. Burke, educational leader; 1942 Dr. George Speri Sperti, scientist; 1943 Francis P. Matthews, Supreme Knight of Knights of Columbus; 1944 Jefferson Caffery, diplomat; 1945 John A. Coleman, Catholic Charities official. (See also CATHOLIC ORGANIZATIONS FOR YOUTH; CATHOLIC RURAL LIFE CONFERENCE, NATIONAL; CATHOLIC WELFARE CONFERENCE, NATIONAL; LIBERALISM; MISSIONS, FOREIGN; PIUS XI; PIUS XII; SOCIETIES AND ASSOCIATIONS; VATICAN CITY STATE.)

Rome

The decade 1937-46 witnessed extraordinary vicissitudes in the capital of Italy. Benito Mussolini planned to make it the centre of a new Roman empire, to be created by means of the alliance of fascist Italy with nazi Germany against the "demo-plutocracies," France and Britain. The strengthening of the Rome-Berlin axis was marked by the visits of Hermann Goering and Constantin von Neurath to Rome in the spring of 1937; the next year, on May 3, the city was bedecked with fascist and nazi banners in celebration of the visit of Hitler. The Romans were somewhat surprised and skeptical, however, at the official adoption of anti-Semitic theories and legislation, and pained by Mussolini's acquiescence in the German seizure of Austria, remarking that Italy had received the goose step (*passo romano*) and Germany, the Brenner pass (*passo Brennero*).

On June 10, 1940, when the German campaign had succeeded in the Low Countries and France appeared to be on the verge of collapse, Mussolini announced the Italian declaration of war amid the applause of an organized claque. The war, however, on which the fascist dictator and his supporters so lightly embarked, brought only disasters to Italian arms in North Africa, Greece and Albania. Reinforcement of the Italian armies by German troops and commanders in 1941 was the first stage of the German occupation of Italy and its capital.

The military reverses of fascism in 1942 and the apathy of the Italian people toward the war furnished the opportunity for a vigorous revival of clandestine anti-fascist and anti-monarchic elements in Rome, as elsewhere in the country. By the opening of the year 1943, the king, too, began conspiring with Generals Vittorio Ambrosio and Giuseppe Castellano to supplant Mussolini with a military government which would be able to negotiate with the Anglo-Americans.

On July 19, Rome itself was severely bombed, after public notice by President Roosevelt that Allied pilots would respect the neutrality of the state of Vatican City. Dino Grandi led a revolt in the grand council on the night of July 24-25, and when Mussolini appealed to the king for support, he was relieved of office, placed under arrest and succeeded by Marshal Pietro Badoglio as chief of the government. The population of Rome greeted the news of Mussolini's fall with genuine demonstrations of joy and hoped for immediate termination of the war.

Badoglio dissolved the Fascist party, promised a return to the pre-fascist constitutional system at the end of the war, and secretly made contact with the Allies. On Sept. 3, General Castellano signed the terms of surrender at Cassibile, hoping that the announcement of the armistice with the Allies would lead to an immediate reversal of sides by the organized armed forces of Italy under the king. When Brig. Gen. Maxwell D. Taylor was secretly brought into Rome on Sept. 6 to concert plans for the landing of an Allied airborne division, he found that General Ambrosio had left the capital, and was expected to return only on the 8th. General Giacomo Carboni was dubious of the ability of the Italian divisions under his command to hold the airports for the Americans, and the projected expedition was cancelled at the last minute.

The Italian government was surprised by General Dwight D. Eisenhower's announcement of the armistice on Sept. 8, and very faulty arrangements were made for the defense of Rome. While the king, Marshal Badoglio and several ministers made their way from Rome by automobile to Pescara and thence by sea to safety behind the Allied lines, General Carboni's conflicting orders permitted the German commander, Field Marshal Albert Kesselring, to occupy Rome, which had been proclaimed an open city on Aug. 14. The capitulation of Rome, which General Calvi di Bergolo authorized on Sept. 10, entailed the practical elimination from the war of Italy's organized armies.

From Sept. 11, 1943, until June 5, 1944, Rome was occupied by the Germans and administered by the Italian fascist republic, which Mussolini proclaimed after his rescue by German paratroopers. Many patriots, however, worked secretly with the Rome Committee of National Liberation, and when the Allied armies liberated the Italian capital, the committee refused to accept Badoglio as prime minister, feeling that he, a marshal of Italy, had left them in the lurch the year before. Ivanoe Bonomi, president of the committee, headed the new ministry which, after some delays, was recognized by the U.S. and British governments.

Rome, once more capital of Italy, welcomed the Consultative National assembly which was formed in Sept. 1945, and which aided the Council of Ministers in preparing for the Constituent assembly elected in June 1946. Lazio, the region of Rome, gave a majority of votes (677,201 to 619,216) in favour of the monarchy, but Italy as a whole decided in the referendum of June 2, 1946, in favour of the republic. The new constitution was to be drawn up by the Constituent assembly, which began its sessions in the capital late in June 1946.

Rommel, Erwin

Rommel (1891-1944), German army officer, was born Nov. 15, 1891, at Heidenheim, Germany. He entered the German army in 1910 as a cadet captain and fought throughout World War I. Some reports said he had joined the nazi party shortly after its inception but these were never substantiated. Rommel, however, was commander of Hitler's personal headquarters during the marches on Vienna, Prague and Warsaw. In 1940 tank divisions under his command played a substantial part in the German victory in France, and in Feb. 1941 he was placed in charge of the Afrika Korps in Libya. Rommel established a reputation as a bold and daring leader, and nearly destroyed the British 8th army before he was stopped at El Alamein in June 1942. In Oct. 1942, however, the British under Gen. Sir Bernard Montgomery launched an offensive that drove Rommel out of Libya and into Tunisia. In March 1943, two months before the Allies destroyed the Afrika Korps in Tunisia, Rommel was called back to Germany for "reasons of health." Later that year he was given overall command of nazi forces in Italy, and in Dec. 1943 he was transferred to France as ground commander of Ger-

Standing at attention, U.S. soldiers watched a colour guard raise a historic U.S. flag in Rome during a Fourth of July celebration in 1944. The flag was the same one flown over the capital in Washington on Dec. 8, 1941, when war was declared on Japan, and on Dec. 11, when war was declared on Germany and Italy

man anti-invasion armies. Rommel was unable to halt the Allied invasion of Normandy in June 1944. He was severely wounded July 17 by Allied strafing planes, which caused his automobile to overturn. On Oct. 15, 1944, a German broadcast officially announced that he had died of his wounds. Later newspaper reports indicated, however, that he had been implicated in the plot of July 20, 1944, to kill Hitler, and had been allowed to commit suicide rather than stand trial and certain execution for his role in the conspiracy.

Roosevelt, Anna Eleanor

Mrs. Roosevelt (1884–), U.S. sociologist, newspaper columnist and government official (widow of Franklin D. Roosevelt, 32d president of the United States), was born Oct. 11, 1884, in New York city, the daughter of Elliott and Anna Hall Roosevelt. She married Franklin Roosevelt, her sixth cousin, March 17, 1905. Mrs. Roosevelt took an active interest in furthering her husband's political career after he was stricken with infantile paralysis. She broadened her social and political contacts, entered local campaign work and kept his interest in politics alive.

Intimate friends of the Roosevelts asserted that her help was invaluable during his first gubernatorial campaign in New York. They declared the president had complete reliance on her observations and said she frequently acted as his eyes and ears on political matters. After his election as president in 1932, she did not take part in his successive electoral campaigns but embarked instead on a vigorous career of speaking and writing. Her newspaper column, "My Day," became widely syndicated.

Mrs. Roosevelt was named (Dec. 19, 1945) by Pres. Harry S. Truman as a member of the U.S. delegation to the United Nations general assembly and was confirmed by the senate the following day. On April 29, 1946, she was elected chairman of the Commission on Human Rights of the United Nations Economic and Social Council (U.N.E.S.C.O.). She frequently clashed with soviet delegates on the definition of freedom. Answering the assertion by Andrei Y. Vishinsky, soviet vice-foreign minister, that the free speech allowed in the refugee camps threatened world peace, she stated that the U.S. and the soviet union had little hope of living together "without friction in the same world" unless both could concede the right of opposition.

Roosevelt, Franklin Delano

Franklin Delano Roosevelt (1882–1945) was born at Hyde Park, N.Y., on Jan. 30, 1882, only son of James Roosevelt and his second wife, Sara Delano Roosevelt. His father, a fourth cousin of Pres. Theodore Roosevelt, was descended from Claes van Rosevelt, a Netherlander, who emigrated to the American colonies in the 17th century.

Young Franklin's first teacher was his mother, a woman of forceful and resolute character. Later, tutors and governesses taught him French and German. At the 1,000-acre Hyde Park estate, he learned to ride, shoot and swim. He also became an expert sailor and developed a passionate interest in naval lore. From the time he was 7 years old, he was taken to Europe annually by his parents and when he was 15, he was sent to Groton, a fashionable preparatory school for boys in New England. There he proved to be a popular, though not an exceptional, student. Upon graduating in 1900, he went to Harvard university, where he established a reputation as an oarsman and was president of the *Crimson*. Although quick and

alert, he showed no special inclination for study. Upon graduation in 1904, he entered Columbia Law school and while studying there, he married (March 17, 1905) Anna Eleanor Roosevelt, a niece of Theodore Roosevelt. Admitted to the bar in 1907, he joined the law firm of Carter, Ledyard and Milburn. Roosevelt devoted himself to his legal practice until 1910, when he was offered nomination for the New York state senate. He was not expected to win, as no Democrat had captured the seat for Columbia, Putnam and Dutchess counties since the Civil War. Roosevelt, however, conducted an energetic campaign. His persuasive speechmaking, his famous name and his winning personality, plus the fact that the opposition was divided, won him the election.

At Albany, the newcomer fomented a "revolt" against Tammany's efforts to secure the nomination of William F. Sheehan, a "party regular," for the U.S. senate. Roosevelt led a group of 19 rebellious legislators who boycotted the party caucus. Because of the boycott, the Tammany supporters could not assemble the number of legislators necessary to approve the nomination, and Sheehan was defeated. Roosevelt was re-elected in 1912.

In 1912 Roosevelt espoused the presidential aspirations of Woodrow Wilson and during the campaign, he became a close friend of Josephus Daniels. When Daniels became Wilson's secretary of the navy, he appointed Roosevelt to an assistant secretaryship.

Roosevelt's activities during World War I brought him some stature in national politics. In 1920 at the Democratic national convention in San Francisco, he seconded the nomination of Alfred E. Smith for president. The convention, however, picked James M. Cox as its presidential candidate and Roosevelt as Cox's running mate. Roosevelt stumped the country, making more than 1,000 speeches, but nevertheless went down in defeat along with Cox. He then resumed his legal career.

The following year (1921), while vacationing with his family at Campobello island, New Brunswick, he was stricken with infantile paralysis and was paralyzed from the waist down. Thus, at the age of 39, he seemed destined to be a bed-ridden invalid. By sheer will-power, however, he built up his strength and within three years was able to move about on crutches. Up to the time of this tragedy, he had displayed no exceptional talents. Friends said that before his illness, he was inclined to be somewhat self-righteous and haughty.

In 1924 he was strong enough to return to his law work and to re-enter politics. At the Democratic convention that year in Madison Square Garden (New York city), he once more proposed Smith for the presidential nomination. Smith, however, lost out to John W. Davis. Four years later, Roosevelt appeared at the convention in Houston, Tex., and again nominated Smith. This time Smith won. Smith in turn wanted Roosevelt to run for governor of New York to bolster the ticket. Roosevelt at first refused on grounds of health, but finally agreed. In the elections, Smith was not only defeated but lost his own state as well; Roosevelt, however, carried New York by a narrow margin of 25,000 votes.

This reversal in their fortunes led eventually to the cooling of the close friendship between the two men, both forceful and strong-willed personalities. The breakup occurred when Smith, in the role of senior adviser, made recommendations to the new governor that the latter was disinclined to accept. Nevertheless, many of Roosevelt's accomplishments in the sphere of social welfare were regarded as an extension of Smith's earlier program. Roosevelt's principal gubernatorial achievements were passage

of several social welfare bills, including an old-age pension plan.

His re-election as governor in 1930 by the unprecedented plurality of 725,000 votes made him one of the leading Democratic contenders for the presidential nomination in 1932. At a time when the nation was plumbing the depths of a catastrophic depression, his record of sympathy for the "little man" had a strong vote-getting appeal. His pre-convention campaigning was astutely handled by James A. Farley; his speech of April 19, 1932, that the nation must devote itself primarily to the "forgotten man" and rebuild from the bottom up and not the top down, won enthusiastic approval from both farmers and labour. At the national convention that opened in Chicago, July 1, 1932, Roosevelt was nominated on the fourth ballot. Breaking with tradition, Roosevelt flew to Chicago to accept the nomination. Arriving in the city on July 2, he made his memorable acceptance speech in which he pledged himself "to a new deal for the American people."

Conducting a thorough campaign, he covered 34 states and made it his duty to talk with Americans in all walks of life. His irresistible optimism charmed many of his listeners, and in the November election he defeated Herbert Hoover by 22,821,857 to 15,761,841 votes, carrying 42 of the 48 states.

When Roosevelt was inaugurated as 32d president on March 4, 1933, a national crisis gripped the country. At least 12,000,000 wage earners were without work and 5,000,000 families—about $\frac{1}{4}$ of the population—were on relief or supported by charity. Industrial establishments operated far below capacity and thousands upon thousands of retail stores were shut. In the rural areas, many embittered farmers destroyed their crops rather than sell them at prices far below the cost of production. Worst of all, a banking breakdown in Michigan caused panic among the depositors in other states and by inauguration day, virtually every bank and stock exchange was closed.

The new chief executive strode into this atmosphere of appalling gloom and in his inaugural speech confidently declared that "this great nation will endure as it has endured, will revive and will prosper. So first of all let me assert my firm belief that the only thing we have to fear is fear itself—nameless, unreasonable, unjustified terror which paralyzes needed efforts to convert retreat into advance."

His brief address helped dissolve the near panic and hysteria that had shrouded the entire nation. Thereupon the president promptly called congress into special session, took the country off the gold standard and charted the reopening of the banks. He cut the veterans' pension system, made more than \$3,000,000,000 available for public works and endorsed legislation designed to alleviate the effects of the economic depression in agriculture and industry. Congress rushed through approval of his measures and at the end of the "100 days" of bold emergency action in which the president and congress worked in almost flawless harmony, the "New Deal" was underway.

Giving impetus to measures for economic recovery, Roosevelt then secured congressional authorization of the Agricultural Adjustment administration (AAA) on May 12, 1933 and the National Industrial Recovery act (NIRA) on June 16, 1933. Under the AAA, the administration planned to allocate federal aid to the farmers who in return agreed to government controls for reduction of crop surpluses. The NIRA, an even more radical reform measure than the AAA, constituted an effort to mobilize nearly all industrialists and workers to joint efforts for increasing employment, raising wages and shortening hours of work.

Neither act, however, worked out as Roosevelt had hoped and both proved unpopular. In May 1935 the supreme court declared the NIRA unconstitutional; the following year, it ruled similarly against the AAA.

Other bills fared better. Among these were the Tennessee Valley authority, the Glass-Steagall Banking act, the Securities act, the Home Owners' Loan corporation and the Farm Credit administration acts. In dealing with relief problems, Roosevelt set up four new agencies—the Public Works administration, the Civilian Conservation corps, the Civil Works administration and the Works Progress administration (which supplanted the CWA in 1935). All were dedicated principally to building public works, thereby giving work to millions of unemployed.

In order to further its policies, the administration ignored current conceptions of budget-balancing and spent funds liberally. The two social groups that benefited most were the farmers and labouring classes. Agriculture benefited materially by the passage of such measures as the Soil Conservation act of 1936 and the second AAA; while labour received concrete advantages from the National Labor Relations act on July 5, 1935, which made collective bargaining mandatory upon both workers and employers. Other pro-labour measures sponsored by the Roosevelt administration were the Fair Labor Standards act and prohibition of child labour in industries operating in interstate commerce.

Though opposed by conservatives and big business, Roosevelt was renominated without opposition in 1936. Popular approval of his New Deal was reflected in the Democratic landslide of that year. He carried all states but Maine and Vermont in the electoral college and rolled up a popular vote of 27,752,309 to 16,682,524 for Alfred M. Landon, the Republican candidate.

Roosevelt's statement in his second inaugural address (Jan. 20, 1937) that measures should be taken to give decent living standards to the "one-third of the nation" that was "ill-housed, ill-clad and ill-nourished" keynoted the social philosophy of his second term. He urged legislation that would promise the states federal aid in unemployment insurance and asked for adoption of a federal old-age pension system. His social welfare program reached its high-point with congressional endorsement of the Social Security act, which he signed Aug. 1935. This was followed by other laws designed to improve the living conditions of the underprivileged, and by the establishment of such agencies as the Farm Security administration, a Federal Housing administration and establishment of the Federal Crop Insurance corporation.

Altogether, congress bowed compliantly to Roosevelt on major issues during the first five years of his presidency. But this "political honeymoon" ended abruptly after Roosevelt sent a message to congress (Feb. 5, 1937), asking for an act which would permit him to add up to 6 justices to the supreme court if those members past 70 did not retire. His request was motivated by fear that the predominantly conservative supreme court would declare invalid certain New Deal measures which he deemed vital. But for the first time, congress balked at following the presidential lead. Many Democratic leaders joined Republicans in opposing the court-packing measure, and in the historic battle that followed, Roosevelt suffered his first major defeat. His plan was rejected, and on Aug. 25, 1937, the president signed one drafted by his opponents, whose only major concession was a provision for retirement of supreme court justices for age. Roosevelt later contended that his

Funeral cortege bearing the body of Pres. Roosevelt past the capitol building in Washington, D.C., on April 14, 1945, along streets lined with honour guards

proposal to add new justices was only a means toward his ultimate objective of "liberalizing" the court.

During his second four years in Washington the president also was occupied with the problems of war and peace occasioned by the aggressive policies of Germany, Italy and Japan. He broke with isolationism in his "quarantine speech" in 1937, and subsequently aligned his sympathies with Britain and France. Thenceforth, the strengthening of United States defenses became one of his major preoccupations. He created a new Atlantic fleet in the spring of 1938 and advocated further substantial expansion of the U.S. naval arm.

After World War II started with Germany's invasion of Poland on Sept. 1, 1939, he voiced his hope that the United States could stay out of the conflict. Simultaneously, he proclaimed U.S. neutrality and banned the export of arms, munitions and war materials to all belligerents. Three weeks later he summoned congress and made a strong appeal to end the embargo. Congress subsequently modified the law to permit shipment of arms under an adulterated "cash and carry" plan. On May 10, 1940, Germany invaded France and the Low Countries. When it became apparent that the Allied armies could not stem the Nazi attack, he adopted a policy of extending all pos-

sible aid to Great Britain. In September of that year, he turned over 50 reconditioned destroyers to Britain in return for 99-year leases on 8 air and naval bases in British colonies in the western hemisphere.

Roosevelt was nominated for a third term at the Chicago convention in 1940. The Republican candidate, Wendell Willkie, accepted the president's foreign policy but vigorously opposed him on domestic issues. Roosevelt carried all but ten states and received a popular vote of 27,241,939, against Willkie's vote of 22,327,226 (about 5,600,000 more than Landon had received in 1936).

Roosevelt's victory was regarded as a majority's approval of his foreign policy and preparedness program. After the campaign, the president speeded the flow of war supplies to Britain and warned on Dec. 29, 1940, that an axis triumph would place the United States in the gravest danger. He also declared: "Our country is going to be what our people have proclaimed it must be—the arsenal of democracy." In his annual message to congress, Jan. 6, 1941, he gave evidence of his postwar thinking in declaring that "in the future days, which we seek to make secure, we look forward to a world founded on the four essential freedoms" (freedom of speech, freedom of religion, freedom from want and freedom from fear). (See FOUR FREEDOMS.)

In keeping with his intention to aid the Allies, the president sponsored the lend-lease bill, which congress passed over the strong opposition of the noninterventionists, on

March 11, 1941. Two weeks later, congress appropriated \$7,000,000,000 for implementing the measure, and war supplies were shipped immediately overseas.

Japan's attack on Pearl Harbor (Dec. 7, 1941) which occurred while Japanese envoys were discussing peace proposals in Washington, was denounced by the president as an act of "infamy." Thenceforth, Roosevelt promptly took steps to mobilize as rapidly as possible the United States for its role in the war against the axis; he said in Jan. 1942, that the U.S. over a two-year period would build 185,000 planes, 120,000 tanks and 18,000,000 tons of shipping. Congress thereupon voted two war powers acts which gave Roosevelt authority to see that these goals were accomplished.

In directing the war effort, Roosevelt was the complete boss, and as commander in chief of the nation's armed forces—a power conferred upon him by the constitution—his was the responsibility for all decisions. It was common knowledge that while he might delegate powers to members of his cabinet or to the directors of wartime agencies, such as Donald Nelson, James Byrnes and Leon Henderson, he made the final decisions and determined strategy.

In the midst of World War II, there was another presidential election in 1944. Maintaining that a continuation of Roosevelt's leadership was indispensable until the war had been won, the Democrats renominated him for a fourth term at their Chicago convention in July. Harry S. Truman was nominated as vice-president over Henry Agard Wallace. Roosevelt's Republican opponent, Thomas E. Dewey, like Willkie, accepted the major premises of the Roosevelt foreign policy but opposed what he called the Rooseveltian "autocracy." Roosevelt's majority in the electoral college was overwhelming, but his popular vote of 25,602,505 was about 1,600,000 less than what he had received in 1940. Dewey's vote of 22,006,278 was only slightly less than Willkie's.

The president continued to give much of his attention to co-operation with the Allies, especially Great Britain and the soviet union. He had several meetings with Winston Churchill on joint problems of strategy and war. Later Roosevelt and Churchill extended their conferences to include the soviet premier, Joseph Stalin. At the Tehran conference (Nov. 28–Dec. 1, 1943), where Stalin first met Roosevelt, the Big Three agreed on the scope and plan of their attacks on Germany and upon method of postwar treatment of the reich. At Yalta, the Big Three conferred for a second time (Feb. 4–11, 1945). There Roosevelt's acceptance of soviet demands regarding the Polish and German borders, on Balkan issues and on far eastern questions, were later harshly criticized. Perhaps the major achievement at Yalta was the agreement to set up a world organization to maintain peace and security and to call a meeting of the United Nations at San Francisco April 25, 1945, to prepare the charter of the proposed organization. (See also INTERNATIONAL CONFERENCES, ALLIED [WORLD WAR II]; UNITED NATIONS.)

Before leaving for his Yalta trip, the president outlined his postwar domestic policy in his annual message to congress, Jan. 6, 1945. In it, he declared that: "We must maintain full employment with government performing its peacetime functions. . . . Our policy is, of course, to rely as much as possible on private enterprise to provide jobs. But the American people will not accept mass unemployment. . . . There will be the need for the work of everyone willing and able to work—and that means close to 60,000,000 jobs."

After returning from Yalta, his health deteriorated rapidly and at the beginning of April 1945, he went to his

cottage at Warm Springs, Ga., to rest. On April 12, he suffered a massive cerebral haemorrhage and died at 3:35 P.M. His body was taken to the White House for funeral services, and on April 15, it was transported to Hyde Park for burial. (X.)

Highlights of the Decade

As one looks over the decade 1937–46, one realizes that 1937 was the year during which much of President Roosevelt's time and thought was spent on financial conditions within the United States. He suffered what was considered one of the worst reverses in congress when the court reform bill was defeated.

But in spite of anxiety over domestic affairs, he was never unaware of the international situation, which was becoming more and more serious. He tried to prepare the thinking of the people of the United States for the war which he saw approaching, and which he was desperately afraid might end by engulfing the United States as well as the rest of the world.

As historians read his "Quarantine Speech" delivered in Chicago on Oct. 8, 1937, they will probably realize that, harking back to the League of Nations, he was trying to apply some of the benefits which he felt could be obtained by some type of world organization for peace, even though none existed.

In spite of the reverses which he suffered in congress and in spite of the fact that those who had opposed him had felt safe to do so because the country was suffering an economic recession, the newspaper reporters were surprised to find that President Roosevelt's personal popularity seemed to hold during the 6,500 mi. trip to the Pacific coast which he started on Sept. 22.

President Roosevelt took these trips in spite of the physical effort which they entailed, because he felt the need of contact with the people, and this was the only way of observing the effect which government policies were having on the individual lives of the people.

President Roosevelt observed more from a train window than most people. He could look at the countryside, gauge what was happening to the land, to the forests and to the people. He returned from every trip not only refreshed by the human contacts, but with new security in his own judgment.

During 1938, he was persuaded to take an active part in trying to defeat for re-election some of the men who had opposed his measures in congress. It is often questionable whether a president is wise to take part in any but his own campaigns. In this year, a number of men returned to congress with deep-rooted resentment against President Roosevelt because of his open opposition, which did not make for greater harmony between the executive and legislative branches of the government.

The European situation was increasingly black, and it was evident that Hitler's mad career was soon going to plunge the European continent into another war. If Great Britain opposed Germany, as it probably would, most people thought that a pattern similar to that of World War I would develop. No one at that time foresaw the complete collapse of France.

The visit of the king and queen of England to the United States in early June of 1939 was an occasion which had a deeper meaning than the usual visit of the head of a great nation, making a polite call upon the head of another great nation.

During the summer of 1939, President Roosevelt made

a final appeal for world peace in a message to Chancellor Hitler and President Ignacy Mościcki of Poland, and King Victor Emmanuel of Italy, and the next day he sent another vain appeal to Hitler.

On Sept. 1, Germany invaded Poland and on Sept. 3, Great Britain declared war. Foreseeing the seriousness of the next few months, President Roosevelt called congress into extra session, on Sept. 13, to revise the Neutrality act.

As 1940 progressed, the third term became a burning question. It seemed probable that President Roosevelt would be drafted, and this happened on July 17, at the Democratic National convention in Chicago.

The author knows that he had thought very seriously about this issue, first because he did not think that in ordinary times a president should have more than two consecutive terms, and next because he doubted very much whether many men could stand the strain of the presidency for more than eight years. This led him, after much hesitation, to ask the leaders to give him Henry Wallace as a running mate, for he felt that Wallace more nearly understood the complex problems that might be facing the administration in case of war than any other man at that time.

One of the outstanding events of 1941 was the meeting in August of President Roosevelt and Prime Minister Churchill with their high-ranking military aides in Argentina bay, Newfoundland. Here the Atlantic charter was drawn up.

The attack on Pearl Harbor on Dec. 7, 1941, which was to force the United States into an active war on two separate fronts, was a great blow to President Roosevelt and his advisers as well as to the country.

In September President Roosevelt's mother died, and this forced upon him many personal responsibilities which he was obliged to neglect because of the press of public business.

In December, Prime Minister Churchill, with his military and naval aides, arrived in Washington. Americans were now in the war and the British were their allies.

The year 1942 was largely given over to preparation with the United Nations' leaders for the maximum war effort. Calls were made upon the American people on the home front for almost unbelievable goals of production. Many in the political opposition thought these goals were unattainable, but in spite of the demands for man power made by the army, the ranks of workers were filled by women, older men and younger boys and girls and the production was obtained.

One can only list the measures taken in quick succession during the year. The budget submitted for 1943 was \$58,927,000,000, and more than half of the nation's income was to go into war expenditures.

In April President Roosevelt proposed a seven point program to congress to keep the nation's economy from inflation: (1) heavier taxes; (2) ceilings on prices; (3) wage stabilization; (4) control of prices for agricultural products; (5) increased buying of war bonds; (6) rationing of scarce essential commodities; (7) the curtailment of installment buying.

As part of this program, he also proposed a \$25,000 limit on salaries after payment of taxes.

On May 30, 1942, soviet Foreign Minister Vyacheslav Molotov arrived secretly in Washington to confer with President Roosevelt and on June 18, Prime Minister Churchill arrived to discuss the war strategy of the United Nations.

Bernard M. Baruch headed a fact-finding commission to formulate a program to meet the emergency created by the rubber shortage. As a result, William M. Jeffers was appointed head of a program to combat this very serious shortage.

In late Sept. President Roosevelt toured the war plants of the country. In early November U.S. forces landed in Africa.

The latter part of Jan. 1943 he made his first trip overseas, this time to meet with Prime Minister Churchill and to confer with Generals Charles de Gaulle and Henri Giraud at Casablanca.

On April 20, he met President Avila Camacho of Mexico at Monterrey, Mexico. In August there was another meeting with Churchill in Quebec on war strategy.

In Nov. came the trip to Cairo, where he met with Generalissimo Chiang Kai-shek and Prime Minister Churchill. At the close of this conference, President Roosevelt proceeded to Tehran, as did Mr. Churchill, and here in the capital of Iran, Marshal Stalin met President Roosevelt for the first time.

Because of his preoccupation with the war, President Roosevelt established on May 28, 1943, an agency known as the Office of War Mobilization, and James F. Byrnes was named head with orders to "keep both our military and civilian economy running at top speed and to eliminate friction from rival agencies."

In early 1944, President Roosevelt was beginning to outline victory to the U.S. people and to give his own vision of what victory would ultimately mean. The author believes that the words of his address to congress should long be kept before the nation. He said the United States would have assurance of freedom from want from "the cradle to the grave." He also promised freedom from fear through the defeat and disarmament of Germany, Japan and Italy and any other nation which coveted a neighbour's territory.

In 1944, President Roosevelt had to make the decision of whether he would run again for the presidency. He accepted the nomination in a radio broadcast while on a trip to confer with General Douglas MacArthur and Admiral Chester Nimitz in the Pacific.

In Sept. he again met with Prime Minister Churchill in Quebec. This was purely a military conference, but President Roosevelt was beginning to think more and more of postwar organization, and a meeting was called in June at Dumbarton Oaks to lay the basis for that postwar organization.

It was after the trip to Tehran that President Roosevelt had a bout with a low fever which took him some time to shake off, but after a stay with Mr. Baruch at "Hobcaw," he returned in fairly good health.

In Feb. 1945 he took his last long trip, to Yalta to meet with Mr. Churchill and Marshal Stalin. On his return he was evidently tired but felt that he had made measurable progress in winning the confidence of Marshal Stalin, and his hopes were high that the three great allied powers would be able to work together to create a permanent peace as they had worked together toward the war victory which was now quite evidently in sight.

On the trip home he was under a great strain because his friend and adviser, Harry Hopkins, was evidently far from well, and his friend and military aide, Maj. Gen. Edwin M. Watson, had suffered a stroke and died on the way home.

For the first time in reporting to congress, President Roosevelt sat to give his speech, but when he left for Warm Springs, Georgia, in April for a holiday, all the doctors felt sure that with rest and care he could go on

through the four years of his fourth term. It was, therefore, a shock to everyone when the news came on April 12, 1945, that he had died in the Warm Springs cottage. For him, the anxieties and the long effort to serve his country and humanity had come to an end.

Roques, Emile

Cardinal Roques, (1880—), French prelate, was born Dec. 8, 1880, at Graulhet, France. He studied for the priesthood, was ordained at the age of 24 and then continued his theological studies at Toulouse and Duesseldorf, later teaching and serving as superior at Catres seminary. He was elevated to the bishopric of Montauban in 1929 and became archbishop of Aix in 1934. A few days before the invasion of Brittany by the German wehrmacht in 1940, he was appointed archbishop of Rennes and primate of Brittany.

During the occupation, he vigorously protested the arrest of the directors of the Christian Agricultural youth and the deportation of Breton workers by the nazi occupation authorities.

He was named to the Sacred College of Cardinals in Dec. 1945 and was created cardinal at the Vatican consistory, Feb. 18, 1946.

Rosenberg, Alfred

Rosenberg (1893-1946), German politician, was born in the Baltic city of Reval (Tallinn), Estonia, and studied architecture and engineering at the Technological Institute of Riga, Latvia. After the end of World War I, he preached the doctrine that bolshevism was the creation of the "Jewish anti-Christ," but his ideas carried little weight until he came in contact with Adolf Hitler. Rosenberg joined Hitler, held the party together after the abortive Munich putsch of 1923 and became the premier nazi ideologist. He preached his racial and political theories in the columns of *Voelkischer Beobachter*, of which he was editor in chief. He also wrote numerous books on the subject, including *The Myth of the Twentieth Century*. Rosenberg was elected to the reichstag in 1930, and after Hitler came to power in 1933 was made reich leader of the National Socialist party. In 1934, he was appointed the fuehrer's deputy for supervision of the entire spiritual and ideological training of the nazi party. After the start of World War II, Rosenberg became a general in the S.S. (elite guards) and the S.A. (storm troops). He was appointed reich minister for the occupied eastern territories on July 17, 1941.

Captured in a Flensburg hospital, Germany, on May 19, 1945, by a British patrol, he was indicted Aug. 29, 1945, as a war criminal by the International Military Tribunal sitting in Nuernberg. He was found guilty of crimes against the peace, war crimes, crimes against humanity and of conspiracy to commit these crimes, and was sentenced to death by hanging, Oct. 1, 1946.

The sentence was carried out Oct. 16, 1946, at Nuernberg.

Rowing

Prior to U.S. entry into World War II, even as late as 1940 and 1941, when it began to appear that war was inevitable, rowing in the United States continued on the same normal course that had been established in the early years of the decade 1937-46. Club rowing was at its height, schoolboy rowing was in the ascendancy, and intercollegiate rowing was on a high plane. True, even prior to 1937, public interest in the Poughkeepsie regatta, the "Kentucky Derby" of rowing, had begun to lag—crowds were progressively smaller than in the 1920s—but much had been done to improve conditions for the crews themselves, principally in the matter of much needed housing, and more crews were being invited and were accepting invitations to compete there. In 1941, the last year of the regatta before its discontinuance because of the war, a field of nine varsity crews, largest in the history of the regatta, participated.

In the intercollegiate field, the year 1937 marked in a way the beginning of a new era. The "Washington" influence, started in 1922 when Edward Leader went to Yale, was strengthened through three coaching changes at major rowing colleges in the east, Harvard, Cornell and Rutgers. At Harvard, Thomas D. Bolles, Washington graduate with an outstanding record for ten years as freshman crew coach at the University of Washington, was appointed head coach, replacing the veteran of the "old school," Charles Whiteside. With him went Harvey Love, former coxswain of Washington crews, as assistant. In the same year Rollin H. Sanford and Norman R. Sonju, both graduates of Washington rowing under Russell S. Callow, went to Cornell as head coach and assistant, respectively, replacing another of the so-called "old school" regimes, James Wray and his son, Clarke; Charles Logg, another Washington man, was made head coach at Rutgers. In 1940, Massachusetts Institute of Technology followed suit by securing Robert G. Moch, coxswain of the Washington Olympic crew of 1936, as head coach, and James McMillen, number five man on the same crew, as assistant. M.I.T. rowing improved vastly under Moch, and later under McMillen, who succeeded Moch upon his retirement in 1945.

Another 1940 change saw Fred Spuhn, Washington oarsman of the early 1920s and previously coach of the Yale 150-lb. crews, going to Princeton as head coach, where he took DeLos Schoch, also a Washington product, as assistant. In Nov. 1946, another important coaching change took place. Norman Sonju, until then assistant coach at Cornell, was appointed head coach at the University of Wisconsin. However, this latest "Washington" appointment was counterbalanced, so to speak, by the retirement of Edward O. Leader as head coach at Yale and the appointment of Allen Walz, lately coach at Wisconsin, to succeed him. With Walz went Joseph Burk, former Pennsylvania oarsman and twice winner of the famous Diamond skulls. This completed the influx of former Washington oarsmen who had turned coaches and brought the number to 20. In most instances these changes of personnel brought varying changes in rowing technique, broadly from the old orthodox English style with its long reach and accentuated body swing to what came to be known as the "arm and

leg" stroke, employing a somewhat shorter reach and considerably less body swing, with the accent on leg drive and arm pull.

The 1937 intercollegiate season was dominated by Washington in the west and Harvard and the U.S. Naval academy in the east. The Washington crew was the same to a man that had won the eight-oared event at the Olympic games in Berlin the year before. It defeated California in April and returned to Poughkeepsie to repeat its victory of the year before. Navy, the only crew to win from Harvard that year, placed second at Poughkeepsie, and Harvard launched its string of victories over Yale at New London, Conn.

It was in this year that Joe Burk began upsetting the timeworn principles of single sculling by winning both the U.S. and Canadian national championships with his "unorthodox" style of rowing. This comprised, broadly, a short reach, a minimum of body swing with very little lay-back at the finish and tremendous leg drive and arm pull combined with high stroking. During the next four years he achieved the enviable record of 46 victories, including the U.S. and Canadian national championships four times and the Diamond sculls in the Henley Royal regatta, Henley, England, twice. He won the right to represent the United States in the Olympic games in 1940, but was deprived of the opportunity when the games were later cancelled.

In England, Oxford won over Cambridge for the first time in 13 years, and England lost in three important events in the Henley Royal regatta. Germany won the Grand Challenge Cup for eight-oared shells, J. Hasenohrl, Ruderverein Ellida, Austria, the Diamond sculls and Tabor academy (Marion, Mass.) of the United States won the Thames Cup for the second successive year.

In club rowing in the United States, the National regatta of 1937, climax event of the season, continued to be open to all amateur oarsmen, but owing to the fact that it was held in July, long after the college crews had broken up for summer vacations, there were seldom, if ever, any college crews competing. Individual championships went to the individual competitors, but the winning club was picked on a point system with so many points for a first place, so many for second, etc., and places in all divisions, 145-lb., intermediate and senior, were considered. This was known as the Barnes Point system, and the club winning the most races in the National regatta each year received the Barnes Trophy. The West Side Rowing club of Buffalo won the trophy in 1937 with a total of 119 points and was able to repeat this success in 1938 and again in 1939. It was not until 1940 that the Penn Athletic club of Philadelphia was able to break West Side's string of victories. Indicative of the rising interest in club rowing during this period was the fact that while in 1937 there were but ten clubs entered in the National, the number had risen in 1939 to 17, and competition was keen. Joe Burk was the outstanding single sculler, representing the Penn Athletic club, from 1937 until he retired from active competition at the close of the 1940 season. The West Side Rowing club owed much of its success during that period to its sweep crews, fours both with and without coxswain, and eights. The other events, double sculls, pair-oared and quad-sculls, were well divided among all of the clubs.

The Schoolboy Rowing Association of America had been organized in 1935 to promote rowing in the high schools and preparatory schools of the country. Schoolboy rowing

was kept active during the war years, and material for most of the championship club crews in 1946 came from that source. In 1937, the annual S.R.A. regatta was held on Lake Quinsigamond, Worcester, Mass., over a distance of one mile. Tabor academy won the senior and junior eight-oared events, and Brooks school of North Andover, Mass., won the three-quarter mi., four-oared race.

In 1938, it was again Washington in the west and Harvard in the east among the college crews. Navy, defeated only by Harvard, in the Adams Cup regatta, came on to win at Poughkeepsie in the record time of 18 min. 19 sec. This left Harvard, undefeated, the mythical national champion. Owing to the fact that neither Harvard or Yale competed at Poughkeepsie, and therefore did not meet the western crews, the Poughkeepsie regatta had not always produced the true national champion. In Great Britain, Oxford again defeated Cambridge. In the Henley Royal regatta, Joe Burk won the Diamond sculls for the first of the two times he was to win it; the London Rowing club won the Grand Challenge Cup and Kent school (Kent, Conn.), of the United States, won the Thames Cup. The West Side Rowing club of Buffalo again won the Julius Barnes trophy in the National regatta with 114 points. Joe Burk was unopposed in the senior single-sculls event, so won by simply rowing over the course. In the Schoolboy Rowing Association regatta at Princeton, N.J., Lafayette High school of Buffalo won the senior eight-oared event, Haverford school of Haverford, Pa., won the junior eights, South Kent school (Kent, Conn.) won the three-fourths-mile, four-oared race, and Harvey Hutcheon and J. G. Godauer, Jr., both of Canada, won respectively the senior and junior single-sculls events.

Full Tide.—In 1939, rowing enjoyed a banner year, particularly in Great Britain, where in July the one-hundredth anniversary of the Henley Royal regatta was celebrated in England. In the United States, the National regatta attracted the largest number of entries in many years and the Dad Vail Rowing association, so named in memory of Harry Emerson Vail, for many years rowing coach at the University of Wisconsin, was organized with C. Leverich Brett as chairman and Allen Walz as secretary-treasurer. The association was comprised of smaller rowing colleges and colleges new to the sport, not yet ready for competition among the major rowing schools. The original membership included Manhattan College, New York, N.Y.; Rutgers university, New Brunswick, N.J.; Boston university, Boston, Mass.; Rollins college, Winter Park, Fla.; Marietta college, Marietta, O.; Dartmouth college, Hanover, N.H.; Williams college, Williamstown, Mass.; Washington and Lee university, Lexington, Ky.; American International college, Springfield, Mass.; and the University of Richmond, Richmond, Va. It was organized to foster rowing among these and other colleges new to the sport, to facilitate the arranging of schedules for races among these crews and to provide for an annual climax race similar to that held at Poughkeepsie among the major rowing colleges of the country. As a result, the first Dad Vail Association regatta was held at Red Bank, N.J., on May 20, 1939, under the auspices of Rutgers university. Seven crews were entered in the varsity race, which was won by Rutgers. Thereafter the Rutgers crews more or less dominated the Vail regatta, and the feeling that they should step aside and enter competition in the major field seemed to be gaining support.

The greatest event of 1939 in the rowing world was the celebration of the centennial of the Henley Royal regatta at Henley, England, mentioned above. The regatta offered competition in heats in nine events, covering a

period of four days, and entries included the largest number of foreign crews in the long history of the regatta. Of the nine events, three were open to eight-oared crews, two, the Grand Challenge and the Thames Cups, to all-comers and one, the Ladies Plate, limited to English crews. The Thames Cup, however, was limited to crews that had not previously won either the Grand or the Stewards Cup for fours. All entries were strictly amateur. The two open events were dominated by U.S. crews, Harvard winning the final in the Grand Challenge from the Argonaut Rowing club of Canada, Tabor academy winning over Kent school in the Thames Cup. There were also three events open to four-oared crews. The Stewards Cup was open to all-comers, the Wyfold Challenge Cup was restricted, with qualification requirements similar to those for the Thames Cup for eights, and the Visitors Challenge Cup was limited to English crews. The excellent Swiss four from the Zurich Rowing club won the Stewards Cup, and two good English crews triumphed in the other two, Trinity hall of Cambridge winning the Visitors and Maidenhead Rowing club winning the Wyfold. The three remaining events were open to all amateurs and consisted of the Diamond sculls for single scullers, the Silver Goblets for pair-oared crews and the Centenary for double sculls. Joe Burk of the United States won the Diamond sculls for the second consecutive year, Trinity hall of Cambridge university won the Goblets, and the Centenary, on the program for the first time, was rowed to a dead heat by the English pair, John Beresford, Jr., and L. F. Southwood, and the powerful Italian combination of J. Scherli and Broschi.

In the intercollegiate field, Cambridge beat Oxford in the annual Putney-to-Mortlake classic, and the University of California left no doubt about its national ranking in the United States by winning the 1939 Poughkeepsie race in the record time of 18 min. 12.6 sec. for the four-mile course there. Harvard again defeated Yale in their annual duel at New London.

For the third consecutive year the West Side Rowing club won the Julius Barnes Trophy at the 1939 National regatta, held at Detroit, Mich. Lafayette High school of Buffalo, Shrewsbury High school of Shrewsbury, Mass., and Brooks School of North Andover, Mass. divided the sweep events in the Schoolboy regatta at Cambridge, Mass., winning respectively the senior eights, junior eights and fours. Michael Popaw of Roman Catholic High, Philadelphia, won the senior single sculls and Edward Smith of Commerce High, New York city, won the junior singles.

War Ebb.—By 1940, rowing, along with other sports in the international picture, began the decline that was to reach its lowest ebb during the war years of 1943 through 1945. Cancellation of the Olympic games in 1940 took much of the lustre from rowing in the United States, but otherwise it continued along normal lines through 1941. Cornell won the mythical Eastern Sprint championship in 1940 but placed second to Washington, recognized as national champion, at Poughkeepsie. That year marked the first of a three-year trial period for Princeton at Poughkeepsie, a definite step toward the improvement of the regatta. Harvard defeated Yale, and Rutgers again won the Dad Vail Trophy. The Nationals were held at Red Bank, N.J., where Joe Burk emerged as national single sculling champion for the last time before retiring from competition, and the Penn Athletic club won the Barnes Trophy over a field of 16 entries. U.S. entries went on to dominate the Royal Canadian Henley regatta at St. Catharines, Ontario, a week later. There was no Henley Royal regatta in England, an important rowing event that continued to be a casualty of the war. The Schoolboy Association regatta

was held at Princeton, N.J. Browne and Nichols school of Cambridge, Mass., won the senior eights and Shrewsbury High school took the junior eights and four-oared events. S. D. Zink of Belleville High school, Belleville, N.J., won the senior single sculls and Edward Smith of Commerce High repeated his 1939 performance in the junior sculls. In 1941 the Poughkeepsie regatta boasted its largest number of entries, nine crews competing in the varsity race, which Washington won. Harvard again defeated Yale at New London, and Rutgers retained the Dad Vail trophy.

The 1941 National regatta was held at Minneapolis, on the Mississippi river, farthest west it had ever been held, and was attended by 16 clubs. Undine Barge club of Philadelphia won the Barnes trophy, gaining all of its 97 points in the 145-lb. division. Theodore A. DuBois of the Winnipeg Rowing club, Canada, succeeded Joe Burk as national single sculls champion. Hun school of Princeton, N.J., Shrewsbury High, and Roman Catholic High of Philadelphia shared honours in the usual three sweep events, the senior and junior eights and the fours, in the Schoolboy Rowing Association regatta at Camden, N.J. Howard McCreesh of St. Thomas More High school, Philadelphia, and John Ryan of Dobbins Vocational school, Philadelphia, won the senior and junior sculling events.

By the spring of 1942, the United States was at war, and the armed services were beginning to make inroads on the number of club and college oarsmen. Still the calibre of the crews was high and competition was good, though limited by the absence of the Poughkeepsie and New London regattas, both cancelled for the duration of the war. Yale and Harvard did meet in a two-mile regatta held at Derby, Conn., which Harvard swept, and shortly thereafter Yale announced that rowing there would be discontinued for the duration. Competition for Washington ended where it began, with a victory over California at Seattle in April.

The National regatta, held at Philadelphia, climaxed the club rowing season in 1942. Joseph Angyall became sculling champion, and the Fairmount Rowing association of Philadelphia won the Barnes trophy in a field of 13 entries. The Royal Canadian Henley, comprising a field of 11 entries, was won by the Argonaut Rowing club with a total of 60 points. The Schoolboy regatta was again held at Camden, N.J., where Lafayette High of Buffalo won the senior eight-oared event. Haverford school of Haverford, Pa., won the junior eights and St. Andrews school of Middleton, Del., took the four-oared race. Larry Kieffer of Roman Catholic High and Joseph Intracaso of William Howard Taft High, New York city, won the senior and junior single sculls.

The 1943 intercollegiate season was short and marked by the absence of Syracuse university, Syracuse, N.Y., as well as Yale. Owing to the shortage of baggage cars for transporting rowing shells, visiting crews for the first time had to row in shells borrowed from the host school. On the west coast, California dropped rowing, leaving Washington without competition, and the Dad Vail Association regatta was cancelled. Club rowing continued but also on a reduced schedule, and performances generally were below par. By the end of the 1943 season, Princeton and the University of Pennsylvania, Philadelphia, Pa., had been added to the list of colleges dropping rowing for the duration, and Harvard announced that it would row informally only, making no trips away from home. The Fair-

mount Rowing association again won the Julius Barnes trophy at the National regatta, held at Philadelphia, and Roman Catholic High school won the schoolboy championship for eights. St. Andrews school won the four-oared event and William Barr of Northeast High school, Philadelphia, became schoolboy sculling champion. Junior events in eights and sculls were not held.

In the summer of 1943, the navy inaugurated its V-12 program for officer training in many of the colleges, and this proved to be a great boon to intercollegiate athletics. As a result, four eastern colleges, Columbia, Cornell, Harvard and M.I.T., plus the Naval academy, were able to maintain rowing in a small way; they developed crews and rowed a greatly curtailed schedule of races during the war. Washington continued rowing through 1944 and 1945, but only as a part of the physical training program for the navy unit there. Club rowing was hard hit in 1944 and 1945 so the National regatta was cancelled in both years. Schoolboy rowing continued, and the Schoolboy Rowing Association regatta was held at Philadelphia both years. Newcomers to the win column in 1944 were Grosse Pointe High school of Grosse Pointe, Mich., in the senior eights, Bennett High of Buffalo in the senior fours, Wyandotte High of Wyandotte, Mich., in the junior fours and John B. Kelly, Jr. of Penn Charter school, Philadelphia, in single sculls. St. Andrews school won the senior eights in 1945, with La Salle High school of Philadelphia gaining its first victories by winning the junior eights and double sculls, a new event in the regatta.

Revival.—It was not until the spring of 1946 that prospects began to look brighter in the rowing world. With the war at an end, former oarsmen began drifting back, and the result was an immediate upsurge in rowing, as in all sports everywhere. In the intercollegiate field, Princeton, Pennsylvania, Rutgers, Wisconsin, California and Washington all returned to competition, and the improvement in performance was immediately noticeable. The eastern crews, including Wisconsin from the "near east," rowed a fair schedule of races, some of them competing in as many as six races. The Poughkeepsie regatta was not renewed, nor was the New London regatta, but Yale belatedly turned out a crew, and Harvard and Yale renewed rowing relations with a mile-and-three-quarters race at Boston, which Harvard won. In lieu of the Poughkeepsie regatta, a nine-crew regatta was held at Annapolis on May 11 over the mile-and-three-quarters Severn river course. A big, well-drilled Wisconsin crew rowed 35 strokes per minute over the entire course to win the varsity race and become the eastern champion for 1946. They repeated their triumph twice more in the east, once at Philadelphia and a week later at Ithaca, N.Y.

The National regatta returned to the rowing scene in 1946 at Philadelphia, the Detroit Boat club winning the Julius Barnes Point Trophy with 135 points. There were 17 events including, for the first time in many years, two pair-oared races. Fairmount Rowing association won the pairs with coxswain, and the Vesper Boat club of Philadelphia won the pairs without coxswain. The Schoolboy regatta was again held at Philadelphia. La Salle High school dominated the racing, winning both eight-oared events, the quad sculls and double sculls. It was the first time quad sculling had been included on the program. West Catholic High of Philadelphia won the senior fours, and Wyandotte High, Mich., the junior fours. The single sculling championships went to Joseph McIntyre of West Catholic High in the senior event and John Erwin of

Northeast Catholic High in the junior.

The highlight of the year was an innovation in intercollegiate rowing, the 2,000-metre International Lake Washington regatta, staged by the University of Washington, the Washington Athletic club of Seattle and the people of Seattle, Wash., and vicinity on June 22, 1946, at Seattle. Eight varsity crews, including Cornell, Harvard, M.I.T., and Rutgers from the east, Wisconsin from the midwest, California and Washington from the west and the University of British Columbia, Vancouver, from Canada, attended, all expenses paid. The race was preceded by a program of water sports and was witnessed by an estimated 150,000 people. All crews rowed in shells borrowed from the University of Washington and built by the noted shell builder, George Pocock, of Seattle. Going into a head wind, Cornell won in the slow time of 7 min. 19.7 sec. with M.I.T. second, Washington third, Wisconsin fourth, Harvard fifth, Rutgers sixth, California seventh and the University of British Columbia last. Less than six seconds separated the first five crews. (R. H. Sd.)

Roxas y Acuna, Manuel

Roxas (1892–), Philippine statesman, was born Jan. 1, 1892, in Capiz, a small town on Panay Island in the Philippines. Educated in English-language public schools, he entered the University of the Philippines college of law, graduating (1913) with an LL.B. He was a law professor at the National university, 1915–16, later returning to his native province to practice. In 1921 he was elected to the house of representatives, later becoming speaker of the house. Roxas was a frequent visitor to Washington as a member of Philippine independence delegations between 1923 and 1933.

In Nov. 1938 Roxas joined the Manuel Quezon cabinet as secretary of finance. Shortly after the Japanese attack on the Philippines, Roxas was assigned Dec. 16, 1941, as liaison officer and aide to Gen. Douglas MacArthur. After the latter went to Australia, Roxas remained for a while on Corregidor and escaped to Mindanao.

Later, Roxas turned up in the pro-Japanese Jose Laurel government as a cabinet minister and helped draft the constitution of the "independent Philippines" that declared war on the United States, and also headed several important government agencies. Roxas, however, claimed that he used his position to carry out secret espionage and sabotage activities; his statements on this subject were supported by Gen. MacArthur. He was subsequently cleared of collaborationist charges. After the end of the war, he was unanimously elected president of the reconstituted senate and campaigned for president in early 1946. On Jan. 21 he was nominated for the presidency by the liberal wing of the Nationalist party. His opponent, Sergio Osmeña, was nominated by the party's conservative wing. In the elections of April 23, 1946, Roxas was elected; he was inaugurated May 28, 1946.

Royce, Ralph

Royce (1890–), U.S. army officer, was born June 28, 1890, in Michigan. He was graduated from the U.S. military academy at West Point in 1914, was commissioned a second lieutenant in the infantry and was promoted

through the grades to lieutenant colonel in 1935. He was raised to the temporary rank of a brigadier general in April 1941.

After the U.S. entry into World War II, Gen. Royce was in command of U.S. bomber forces in Australia that carried out raids against Japanese bases in the Philippines in 1942. Promoted to temporary rank of a major general in 1942, he was made commander in Sept. of that year of the 1st U.S. air force at Mitchell Field, New York. The following April (1943) he succeeded Gen. Lewis Brereton as commander of U.S. forces in the middle east. Later, Gen. Royce relinquished this post and devoted most of his energies to improving U.S. relations with Saudi Arabia. In 1944, after the Normandy landings were under way, it was disclosed that Gen. Royce had supervised the establishment of a French-U.S. air force.

Rubber

In the interval between the two world wars the rubber industry alternated between feast and famine. Crude rubber prices wavered between \$1.25 and less than three cents a pound; dealers in tires and tubes were constantly cutting prices, while the efforts of large research staffs made the end-products more serviceable and more saleable. All over the world rubber goods were made more plentiful, of better quality and at lower cost, so that rubber served more uses each year. This urge to find new outlets for the large supplies of natural rubber prevailed during the periods of abundance, frequently even when the uses did not seem to be based upon the superiority of rubber. Such, for example, were the attempts to make highways and composition roofs despite the poor aging of rubber on exposure to sunlight. In the decade 1937-46 there was no scarcity of rubber from natural causes, but only from artificial causes, such as war or government restrictions placed upon its sale.

Table I.—World Production of Natural Rubber, 1937-41

	Short tons*
1937	1,306,000
1938	975,000
1939	1,108,000
1940	1,562,000
1941	1,680,000 (est.)

*Although the long ton of 2,240 lb. is used exclusively by the industry as the unit of measure for raw rubber, the short ton is employed in this article at the request of the editor in the interest of uniformity.

Shortages of this nature seemed destined to be of short duration. In proportion to their severity they brought to bear forces which corrected them and tended to make rubber more plentiful. Thus, the pattern of the restriction invoked by the British (Stevenson act) in 1922 had brought more rubber from the Dutch possessions and initiated the Firestone estates of nearly 100,000 ac. in Liberia. Again, after 1934, the joint restrictions of the British, Dutch and French governments, under the workings of the International Rubber Regulation committee, had forced out from the native estates of the far east large amounts of rubber which could be kept off the market only by a high export tax paid by the native producer. Moreover, under the threat of the control of world markets, timely research was launched in many laboratories in Germany, the U.S.S.R. and the United States on synthetic rubber which gained full fruition only during World War II. Although this effort had been steady and systematic for 20 years, the results of the scientific studies were closely held to small-groups in each of the countries. The fall of Singapore and the Netherlands Indies to the Japanese in 1942 stopped at its source the production of 90% of the world's rubber, thus creating

the most acute shortage in the history of the industry. The successful and timely researches which had been conducted on synthetic rubber, its source materials, its properties and uses, were integrated into a vast production program. In the United States alone by 1945, after a 3 years' construction program, the capacity to make synthetic rubber exceeded 1,000,000 tons a year, a potential which had taken the plantation industry a full 25 years to achieve.

Table II.—Natural Rubber Imports (short tons)

	United States	United Kingdom	France	Germany	Japan	Canada
1937	663,631	101,932	66,161	109,950	69,670	40,417
1939	544,710	77,543	72,102	84,000*	47,433	36,409

1945	144,400	—	—	—	—	—

*Estimated.

From 1936 until 1941 the great bulk of rubber goods was made by machine methods which tended steadily to become automatic. Ingenious tire-building units reduced human effort to a minimum. Huge conveying hooks carried the unvulcanized tires to watchcase or dome-type vulcanizer units where they were cured in steam-heated moulds under pressure and were thence again carried on continuous conveyors to the warehouse. By 1940 virtually all tire-building steps were capable of being completely mechanized. The skilled workman of the former decades had gradually given way to machine and mass production methods.

With the need to supply rubber goods for war after 1939 came the return to hand-built articles such as fuel cells with their novel sealant plies, gas masks, tank tracks, delicate diaphragm discs, close-fitting sealing rings and the unending millions of parts for assembly lines in other war factories. Labour had to be trained to master skills which had been discarded. Even the mechanized assembly lines had to be either newly equipped or replaced to fit them for new types and sizes of product. By the end of the war in 1945 the shortage of labour had become more acute than that of critical materials like carbon black, tire cord and natural rubber. Reconversion steps after V-J day in Aug. 1945 were very rapid. The industry returned promptly and extensively to the mechanized type of operation and exceeded all estimates for fabrication of articles during 1946.

Natural Rubber.—The primary commodity for fabrication of rubber goods prior to 1943 was natural rubber, about 97% of which was grown on the estates and native gardens of the far east, in equatorial Malaya, Java, Sumatra, Borneo, Indo-China and Ceylon. After 1941, as has been noted, the Allies were forced to change from natural to synthetic rubber, and subsequent to 1943 the bulk of their rubber supplies had to be synthetic. Table III shows the amount of natural rubber consumed on the basis of tons per year and as a percentage of the total natural and synthetic rubber for the United States, which normally used about one-half the world rubber production.

Table III.—Natural Rubber Consumed in the U.S.

	Short tons	Percent of total (natural and synthetic)*
1937	609,000	100
1939	663,000	100
1941	868,000	100
1942	422,000	96
1943	356,000	65
1944	162,000	20
1945	118,000	15
1946 (est.)	295,000	29

*Excluding special purpose synthetic rubber.

A glance at Table IV serves to show the abrupt change in the source of rubber during ten eventful years, but it needs to be noted that the meaning of the term "rubber" had also changed. Rubber was now regarded as a state of matter rather than a specific material. Natural rubber is only one of the many polymers which can be made to serve the wide uses which make rubber important in commerce. It is not alone in its ability to confer cushioning with long flex life on wear-resistant structures like tires—an attribute which was now shared with several of the modern synthetic rubbers. Yet natural rubber at the end of the decade was better than other polymers in combining elasticity and rebound, extensibility, resistance to stiffening at low temperatures, good properties at elevated temperatures and low heat generation on flexing. A polymer identical with natural rubber had never been made in the laboratory.

Although natural rubber came mainly from the tropics, extensive trials were made to grow it elsewhere. In White Russia prior to the German invasion in 1941 the planting of more than 700,000 ac. of Russian dandelion (mainly *kok-saghyz*) was being planned to ensure the soviet republic a minimum of about 30,000 tons of rubber. In California during 1942 and 1943 nearly 30,000 ac. of guayule seedlings were planted. Experimental projects were also launched to grow *Cryptostegia* in the Caribbean region, to grow the Russian dandelion in the United States and to continue work on the recovery of rubber from goldenrod and other species of plants native to North America. All of these projects were handled by the U.S. department of agriculture. Rubber could be derived only at high cost from these sources, which were not competitive with tropical or with synthetic rubbers. Tropical America, once the origin of most of the rubber used in world trade, failed to step up production appreciably under the stress of World War II. Attempts such as those of Henry Ford in Brazil to bring large areas under cultivation and tapping did not succeed because of the blight called South American leaf disease. Inducements of a monetary nature to stimulate native tappers to bring in more wild rubbers were singularly ineffective at the time rubber was most needed, and the Rubber Development corporation, which had handled these functions during the war, indicated that success had been lacking in these efforts. Table IV shows the rubber produced in the western hemisphere each year from 1941 through 1944, and for comparison the production for 1910, when the price of rubber reached its peak, and for 1918, the last and least-productive year of World War I.

Table IV.—Western Hemisphere Production of Natural Rubber*
(short tons)

	1910	1918	1941	1942	1943	1944
Amazon countries	46,100	29,700	19,854	21,731	27,533	34,365
Mexico—guayule and other types	19,590	3,110	6,061	8,695	9,333	10,487

*Chiefly wild rubber.

Synthetic Rubber.—After World War I there was great activity in research on synthetic rubber. The Germans supported the lead of I. G. Farben researches which culminated in 1939 in the erection of the huge research laboratory in Leverkusen, a venture shared jointly by industry and the 3rd reich. The emulsion copolymers of butadiene-styrene, styled the lettered Bunas, were the net result of this joint effort. Buna S, the early German tire rubber, was a copolymer made from about 75 parts of butadiene and 25 parts of styrene charged into a stirred pressure vessel and allowed to react under specific conditions in the pres-

ence of water, an emulsifier and a catalyst. Buna S, designed for use in tires, was expected to replace natural rubber in general use. The Germans tried hard to make their synthetic polymer match the elusive properties of natural rubber but without marked success. In the midst of war they developed a series of polymers like Buna S, such as Buna S₁, S₃, S₄, for which claims of better properties and longer service life were made. These were but variations on the theme of emulsion copolymerization of butadiene and styrene. Buna SS, with a higher styrene ratio, was also made for electrical insulation, and for some uses where it lent itself to the more perfect forming of articles. Buna N, made by the same technique as Buna S, was designed with butadiene and acrylonitrile as the components of a copolymer with improved resistance to oil and to sunlight over the other Bunas and over natural rubber compositions. After 1937 it was exported under the name Perbunan and found ready acceptance in other countries. The name "Buna" was suggested by the work of earlier chemists who even prior to World War I had polymerized butadiene (Bu) by the use of sodium (Na). Reverting to the liquid or mass polymerization method of this early work, the German I. G. Farben chemists also produced the numbered Buna rubbers, such as Buna 85 and Buna 115, which they at one time found useful as softeners for the tougher lettered Bunas. The number referred to the number of thousands in one molecular weight unit. Thus, Buna 85 signified a polymer with 85,000 molecular weight.

Production figures for synthetic rubbers in Germany revealed only slight bombing damage until fairly late in the war. The three large factories for the synthesis of the Bunas were located on the lower Rhine at Huels (in the postwar British zone of occupation), at Ludwigshaven on the upper

Table V.—German Production of Buna Rubbers
(short tons)

	Buna S	Buna N	Numbered Bunas
1939	22,400	1,260	788
1940	40,500	2,085	1,562
1941	71,400	2,900	2,153
1942	102,250	3,150	2,928
1943	121,000	3,970	3,878
1944	107,550	3,470	3,240

Rhine (French zone) and at Schkopau (soviet zone). Despite the destructive bombings of these three plants, the steel equipment in which the chemical synthesis was conducted came through little damaged. In large part it was available for operation after a brief period for refitting the

Unloading a shipment of raw rubber from a river boat at Mañaos, Brazil, in 1943. Brazilian wild rubber contributed to the stock pile of the United States and its allies during World War II

feed and delivery lines. In the main the large-jacketed reactors did not suffer damage, and by the early autumn of 1945 the fabrication of Buna rubbers was being resumed on a small scale.

Little was known about the synthesis of rubber in the soviet union, although the world was indebted to a Russian chemist, S. V. Lebedev, who was a pioneer in this field. During World War II the soviets made butadiene polymers, called SK rubbers, in two ways, both using alkali metal (presumably sodium) as a catalyst. In one case the liquid, in the other the vapour, butadiene was converted to a polymer. Just why both types were needed and whether one was superior to the other was not revealed. During the war the soviets were licensed by the E. I. du Pont de Nemours & Co. to make Neoprene, a polymer of chloroprene, although an earlier soviet version of this polymer, named Sovprene, had been reported. It was probably not inaccurate to infer from the meagre reports issued that the soviets preferred natural rubber to any type of synthetic, that their chemists had tried to make emulsion copolymers like Buna S, that alcohol was a favoured raw material for their operations and that the main product of synthesis was their "SK" polymers made from butadiene. After the war a few thousand pounds of soviet synthetic rubber were shipped to the United States for large-scale trials.

In the United States the earliest fabrication of synthetic rubber and of articles made from it was credited to R. B. Earle and L. P. Kyrides (Kyriakides) in 1910. These scientists, employed by the Hood Rubber company (later a division of the B. F. Goodrich company), Watertown, Mass., made polymers which they obtained from alcohol or acetone by expensive processes. The polymer thus made was used to make articles such as soles and heels, which were sold as finished products. After 1925 many new polymers with properties more or less like those of rubber were perfected by U.S. chemists. Some of these, such as the plasticized polyvinyl esters (Koroseal, Vinylite), were often listed as plastics, but their performance in uses once rendered only by vulcanized rubber entitled them to a position in the synthetic rubber field. Neoprene (1931), a polymer of monochlorobutadiene introduced by E. I. du Pont de Nemours & Co., earned a position among special-purpose rubbers with excellent properties in resistance to oil and sunlight. Thiokol (1928), a polyalkylene polysulphide, had a more limited range of usefulness with peculiarly favourable performance in certain lacquer solvents. Hycar (B. F. Goodrich company), Chemigum (Goodyear Tire and Rubber company), Perbunan (Standard Oil Development company) and Butaprene (Firestone Tire and Rubber company) were all nitrile-butadiene copolymers of the oil-resistant type which came into very active demand in solvent and oil-resistant structures, largely replacing natural rubber. Government rubbers—GR-I (butyl), mainly for inner tubes, GR-M (Neoprene) and GR-S, a general purpose copolymer of butadiene and styrene—were made in huge factories erected during World War II. Silicone rubbers, introduced by the General Electric company, had the ability to withstand high temperatures without loss of shape or insulating properties.

Few people in 1939, even after the invasion of Poland by Hitler's legions, gave serious thought to the threat of war against the world's supply of rubber. At the end of 1939 stocks of crude rubber in the United States had declined to 140,000 tons from more than 225,000 tons at the end of each of the years 1936, 1937 and 1938, and more than 340,000 tons at each year-end for the period 1931 through 1935. In order to build up domestic stocks, representatives of the U.S. industry and the Reconstruction Finance corporation recommended action by congress which resulted in the creation of the Rubber Reserve company on June 28, 1940. By virtue of a series of agreements with the International Rubber Regulation committee, stocks of rubber on hand by April 1942 had risen to 700,000 tons.

In June 1940 the B. F. Goodrich company brought out Ameripol tires with more than half of their rubber a U.S.-made synthetic polymer; and Standard Oil Development company announced butyl rubber, a product of U.S. origin. These announcements stimulated much public interest. The National Defense Advisory committee, starting in Aug. 1940, held meetings with representatives of industry which led to the engineering plans for a program of 112,000 tons of synthetic rubber a year. Since no private enterprise appeared willing to risk the capital to make this large operation possible, the plans and data were turned over to Reconstruction Finance corporation (*q.v.*) by the National Defense Advisory committee in Oct. 1940. These data comprised reports on the most satisfactory types of rubber for tires and tubes, the production processes to be used, the availability of the raw materials, the critical construction materials required for the plants and the time required to build them as well as the size and location of the plants. The Reconstruction Finance corporation sought answers to a complex maze of questions from the four major rubber companies and the Standard Oil Development company, all of whom were actively interested in synthetic rubber. It became apparent that huge sums of money were required, which the government was unwilling to approve. Consequently, the program was scaled down to less than half its original size, to 45,000 tons, which was authorized in May 1941. The contracts called for having 4 plants built, each with a total initial capacity of only about 11,000 tons, with no provision for raw materials with which to operate these plants before November. Meantime, privately financed plants had been expanded to a rated capacity of more than 30,000 tons by the end of the year. When Japan attacked Pearl Harbor, the government program for synthetic rubber proved totally inadequate. In Jan. 1942 this program was increased tenfold, and again doubled during the first half of 1942 after the fall of Singapore to a total of 900,000 tons, comprising 790,000 tons GR-S, 65,000 tons GR-I (butyl) and 45,000 tons GR-M (neoprene). With slight changes these programs when completed had a demonstrated capacity of 1,120,000 tons a year. Even after their authorization the public was not convinced that they could be completed in time to supply the needs of the Allies in a global war. Hence, on Aug. 6, 1942, the president appointed a Rubber Survey committee to study the rubber situation and make recommendations. This committee consisted of B. M. Baruch, chairman; J. B. Conant, president of Harvard university; K. T. Compton, president of Massachusetts Institute of Technology and a staff of other experts. After holding meetings and receiving reports the committee on Sept. 10, 1942, submitted to the president a report with specific recommendations concerning the rubber program, which called for the rationing of gasoline and

tires, for limiting speeds to 35 mi. per hour and for "bulling through" the gigantic synthetic program with the reorganization and consolidation of the government agencies then dealing with rubber. The creation of a new office under the War Production board, that of rubber director, was effected by the president's order in Sept. 1942. William Jeffers was appointed to that office, which he held until late 1943, when he was succeeded by Bradley Dewey.

The synthetic rubber program required butadiene in amounts of 600,000 tons a year, 220,000 tons from alcohol and the rest from petroleum feed stocks, 187,500 tons of styrene, as well as smaller amounts of chemicals, catalysts and solvents. In addition to the plants for the starting materials, there were polymerization plants for GR-S, and plants of entirely different design for the manufacture of butyl and neoprene. There were 51 plants designed, built and placed in operation by 49 rubber, chemical, petroleum and industrial companies under the supervision of Rubber Reserve company. The estimated plant investment was in excess of \$700,000,000. In 1945 expenditures for materials, utilities, services, etc., were about \$2,000,000 a day. All of these operations involved full co-operation of the industry with pooling of patents, exchange of technical information and organization of research and development projects under contract with the government. These government-owned factories in the synthetic rubber program were distributed widely in order to make them accessible to raw materials or to the consumers of the finished product, with the heaviest concentration of facilities near the Gulf of Mexico. Plants were located in Connecticut, Pennsylvania, Ohio, West Virginia, Kentucky, Louisiana, Texas, Arkansas and California. The Canadian plant at Sarnia, Ont., under the supervision of the dominion government, had a designed yearly capacity of 33,600 tons of GR-S and 7,800 tons of butyl, with facilities for butadiene, styrene and isobutylene manufacture. It was announced in 1946 that this plant would continue to supply synthetic rubber

under government management and that excess production capacity beyond the needs of the dominion would supply polymers for world markets.

The ultimate disposition of the government synthetic rubber program in the United States had not been determined by Dec. 1946 although a preponderance of public opinion appeared to favour its sale to private industry. On Feb. 19, 1946, in the first report of the Inter-Agency Policy Committee on Rubber, Chairman W. L. Batt stated, "Private ownership and operation of the synthetic rubber industry should be a major objective." This report also made recommendations on the reserves of synthetic and natural rubbers to be maintained in line with the national interest. It specified that as a minimum there be maintained in production and use, regardless of cost, sufficient synthetic rubber capacity to supply one-third of the country's needs but not less than 280,000 tons per year. The plants maintained in production should "comprise the most efficient and low-cost of existing facilities." Exclusion of plants based upon alcohol was thus indicated. Such efficient plants as were in excess of the production minimum program and had not been acquired by private industry were to be maintained by the government in adequate stand-by condition for use only in a national rubber emergency. At least one of these stand-by plants was indicated for operation with alcohol feedstocks.

Textiles.—The need to combine rubber with supporting materials had been known from the start of the rubber industry. For years the leading textile material had been cotton cord, the strengthening element of tire carcasses. By 1940 rayon cord for truck tire carcasses had wide acceptance. Hence, it was necessary to set up facilities for its manufacture on an expanding scale to ensure that it would be in large supply to go with the synthetic rubber from the government plants. Rayon cord was specified because of its uniformity, good fatigue life, resistance to heat and flexure and ability to yield tires which would remain sound after several recapping operations. In the critical period of rubber shortage, the use of rayon gave tire designers the option to crowd more load-supporting cords per inch of width into combat and heavy-duty tires, thus conserving rubber and extending the factor of safety against blowout. The balance between GR-S plies, which grew hot faster than rubber under given speeds and loads, and the rayon plies,

Unit of a dummy fleet made of rubber and canvas, this L.C.T. was assembled and inflated on an English beach. It was revealed on Dec. 5, 1945, that entire armadas of invasion craft carrying dummy tanks, artillery and other equipment, were used along the English channel to confuse axis observers before D-day

which withstood heat better than cotton, made a dual change in design imperative. At one time during World War II 50 different projects to assure prompt supplies of tire-grade rayon were given the necessary priorities. In support of the military requirements, both William Jeffers, rubber director, and the Truman committee made clear the need for ample facilities for both rubber and rayon manufacture. By 1946 the capacity of rayon fabricators to produce yarns of tire grade (high tenacity) exceeded 200,000,000 lb. a year.

*Source—Rubber Manufacturers association.
Total tire production was not available, except for 1944 and 1945, but since textile consumption was reported only for automotive casings (passenger car and truck-bus), this table gives the correct comparison.

By 1946 nearly half of all rayon produced in the United States was in the form of tire yarns, mainly in 1,100 denier size, and cotton cords had been largely replaced by rayon cords for truck and bus tires. In passenger car tires cotton cords continued to make up the bulk of the textiles employed, but to a limited extent rayon was being used. The war brought a noteworthy change in the fabrication of tire cords, a change from the assembly of cotton staple into yarns and cords by conventional cotton mill practice to the much-simplified doubling operations, starting with continuous filament rayon yarns on huge cylindrical beams.

The use of nylon yarns for special structures, like airplane tires and human parachutes, grew in importance during the war years largely because of the superior tensile strength, elongation and impact strength of nylon over other available materials. Thus, strong structures with great flexibility and economy in weight were successfully made for many strategic uses. Nylon, a product of synthesis from abundant materials like coal, was exceptional among filamentary forms of matter in showing little tendency toward brittleness and fatigue. Its properties thus bordered on those of rubber, and its combinations with the latter gave structures with unusual properties. Fortisan, another of the newer synthetics, made from cellulose acetate, was of comparable strength to nylon but much lower in its limit of elongation. In composition it resembled cotton or rayon.

Among the interesting textile materials for composite structures with rubber or with plastics was Fiberglas, a finely spun continuous filament of glass. With requirements for high strength, good electrical properties and ability to withstand temperature, Fiberglas was found superior to other textiles. Such composite structures often showed remarkable properties under impact.

Another supporting material which was used successfully in the construction of tire carcasses was steel wire. The Michelin company in France manufactured tires of this construction, and several large tire companies in the United States used wire where tires for moving heavy loads at low speeds, such as those for earth-moving equipment, were in demand.

Carbon Black.—Beginning about 1912, it was recognized that the life of tire treads against abrasive wear could be extended vastly by the incorporation of channel black with the rubber. Channel black is made by the incomplete burn-

ing of natural gas in small flames which impinge on metal surfaces to form coatings of soot. Tires made before World War II had carcasses of rubber which carried little or no carbon black, since its use in the inner plies favoured unwanted heat effects. With the advent of GR-S, it was necessary to use inner plies which carried generous amounts of carbon black to ensure the requisite strength and other physical properties of tire performance, and also to employ carbon black as usual in the outer tread to give resistance to wear. The resulting practice involved the consumption of 30-100% more carbon black per tire with synthetic than with natural rubber, but it also provided for the selection of varieties of carbon black which were quite different, for the carcass inner plies, from the channel black which was accepted as best for treads. Furnace blacks of two types had been perfected before World War II—the thermal decomposition types made by the simple application of high temperature to natural gas in a closed chamber, and the combustion types in which the gas and air were fed through a furnace where soot was liberated to the precipitator and collector system. The combustion types were usually intermediate between channel black and the thermal decomposition types in yield, in particle size and in reinforcing effects.

The demand for adequate supplies of black to go with GR-S forced an increase in facilities to make carbon black. Because of the smaller steel requirements, the higher yield obtainable from natural gas and the shorter time of construction, the War Production board specified furnace blacks. The productive capacity for this type of black began to exceed that for the impingement type, channel black. Attempts by a few suppliers to improve the quality of furnace blacks resulted in the production of "fine furnace" types or "structural blacks," one variety of which was made by burning oil.

The production of channel black was located in remote districts for good reasons. It contaminated the surroundings with air-borne soot, and most states restricted black production to "sour gas," not wanted in other commercial fields and not always purifiable for other uses. Most of the world's carbon black during the decade 1937-46 was made in Louisiana, Texas, Kansas, Oklahoma and California, subject to legislative restrictions varying somewhat from one state to another. As long as carbon black was made from waste gas, most states encouraged its manufacture to favour free enterprise and to secure taxable income. Natural gas was widely distributed in large gas mains to provide industrial and domestic fuel, and in most states gas which could be used in the mains was not permitted to go into carbon black. Methods were also discovered by which natural gas could be converted chemically to gasoline, a practice legally favoured ahead of black production. The producers of carbon black gradually increased the yield of product by more efficient methods but mainly as a result of the fact that the ratio of production of furnace blacks to channel blacks advanced yearly during the decade. Channel blacks conferring good tread wear are of extremely small average particle diameter (about 250 Angstrom units, 60-billionths of an inch), while the particles of furnace blacks have diameters from about 400 to 2,500 Angstrom units. The finer the particles required the lower is the yield. No way was found to gain high yields of a furnace black equalling the quality of the channel grades.

When channel blacks are dispersed in rubber the area of contact between the black and the rubber is extremely large, amounting to 11 ac. per pound of black or about 40

ac. for a tread of the most widely used passenger tire, size 6.00x16, which is about 12,000,000 times the usual area of tread rubber in contact with the road, 22 sq.in. Against the criticism of the waste involved in black manufacture attention was called to the fact that to make a set of tires run safely in the customary life of 20,000 mi., 75 cents worth of black from 35 cents worth of natural gas was required while the cost of the motor fuel involved in running the car would be about \$100.

Reclaimed Rubber.—Scrap rubber in the form of discarded tires, inner tubes, industrial belts, hose and footwear comprised the source of the great bulk of all reclaimed rubber during the decade 1937-46. The reclaiming process consisted of the removal from the scrap of metal, fabric or nonrubber components, either mechanically or chemically, followed by a treatment softening the vulcanized rubber and preparing it for incorporation with unvulcanized fresh rubber and other ingredients commonly used, such as sulphur, pigments and softeners. Normally reclaim was used as an aid in the processing of rubber and to stabilize the cost of ingredients rather than to cheapen rubber products. During World War II, besides the normal channels of consumption in such uses as industrial products and tire carcasses, reclaim was fortunately capable of being used largely to supplant rubber in tire-treading compositions. For several months during 1943 and 1944 in the neighbourhood of 30,000,000 lb. of camelback, unvulcanized rubber stocks of proper shape, for recaps and retreads were supplied by the industry each month in the United States alone, thus conserving the mileages latent in the carcasses of used tires and averting the need for new tires of rubber or of GR-S. This amount of camelback was enough for 2,500,000 passenger tires and 630,000 truck tires per month. A nation-wide scrap rubber collection, initiated by Rubber Reserve in 1942, received such generous response that no repetition was needed, although several shipments of scrap tires were made from England to the United States during the war years. The reclaiming industry was almost unique among the suppliers of necessary commodities to the rubber industry in not being involved at any time during the war in critical shortages. This excellent production record was cited by the rubber director late in 1943. The great benefit to the U.S. war effort from the use of reclaim came in the years 1942 and 1943, with lessening demands in 1944 as the huge output of GR-S was made available. Scrap tires based upon GR-S required a

quite different process of reclaiming as compared with those which prevailed with the scrap from natural rubber. Wherever Neoprene or other types of specialty synthetic rubber scrap were encountered, other and different methods of reclaiming were indicated. Timely reports of success in the use of reclaim from GR-S scrap and from mixtures of GR-S and natural rubber scrap appeared during 1946.

Other Raw Materials.—Both natural and synthetic rubber compositions need to be blended with sulphur, accelerators, age resisters, softeners and mineral ingredients to achieve mixtures which handle well and vulcanize to give the required properties. The underlying behaviour of the rubber hydrocarbon is the same whether natural or synthetic rubber is employed, and limited choices are possible in the selection of specific ingredients.

In general, compositions of GR-S require more softener and less sulphur than those of natural rubber. With both rubbers age resisters are consistently used to protect against deterioration of the product. Government plants for GR-S required age resisters, soaps (about 100,000,000 lb. a year) and incidental chemicals which were supplied by private industry. In the huge government program for GR-S the production of sulphur, accelerators, age resisters, softeners and emulsifying agents involved almost no investment of public funds.

Finished Products.—Tires and Inner Tubes.—The critical problem of the rubber industry in World War II was transportation. The Baruch report (Sept. 1942) stated:

Tires on civilian cars are wearing down at a rate eight times greater than they are being replaced. If this rate continues, by far the larger number of cars will be off the road next year and in 1944 there will be an all but complete collapse of the 27,000,000 passenger cars in America. . . . We find the existing situation to be so dangerous that unless corrective measures are taken immediately this country will face both a military and a civilian collapse.

This report also summarized in tabular form the knowledge pertaining to the conversion of synthetic rubbers and reclaimed rubber into tires and recap material for tires, as shown in Table VIII.

Great credit was due to chemists and engineers of the rubber industry for their ingenuity in making tires from relatively unfamiliar materials. Sturdy constructions were arrived at by combining diverse novel elements, such as GR-S, rayon and certain carbon blacks. Adequate service tests were run promptly on these tires to ensure their satisfactory performance. All of these steps would have been a huge task under normal conditions, but with the threat of entire collapse of the Allies, time was of the essence.

Table VIII.—Comparison of Synthetic Rubbers and Reclaimed Rubber with Crude Rubber as a Tire and Recap Material*

	Manufacturing efficiency	Tread wear	Carcass failures	Suitability as a recap	For inner tubes
Buna S (new tires and recaps)	Good—Mixing 40–70% Building 80–100% Curing 100%	Good—Tests show about 90% mileage of crude rubber.	None—If 10% crude rubber is used.	Good—Tests show about 90% mileage of crude rubber. Curing time about the same as crude rubber.	Apparently satisfactory.
Neoprene (new tires and recaps)	Good—Mixing 40–65% Building 75–100% Curing 50%	Good—90% mileage of crude rubber at normal speeds; 125% under severe service.	None—No carcass failures reported in tires tested recently. Some failures in earlier tests.	Good—Tests show 90–110% mileage of crude rubber recaps. Curing time longer.	Apparently satisfactory.
Butyl (new tires)	Good—Mixing 100% Building 100% Curing 70–75%	Fair—40–50% of mileage of crude rubber.	Frequent—65% of first tires failed largely because of blisters which developed in the manufacturing process.	Promising—Adhesion with crude rubber was poor at first, but a recent development appears to have overcome this difficulty.	May be developed, but not yet satisfactory.
Flexon (new tires)			(Omitted)		
Thiokol (recaps)			(Omitted)		
Reclaim (new tires and recaps)	Good—Equal efficiency in milling, etc.; cures somewhat faster than natural rubber.	Poor—About 20–25% mileage of crude rubber.	Infrequent.	Good—Curing time same as for crude rubber.	Fairly satisfactory.

*Report of the Rubber Survey committee (Baruch, chairman), Sept. 10, 1942. Comparisons were based on average experience in latest tests, operating at speeds around 40 m.p.h. The mileage life of a crude rubber tire at this speed was considered to be about 35,000 mi.

A primary step in the manufacture of GR-S type synthetic rubber is the coagulation of synthetic rubber latex by salt and acid, which joins the small particles into larger crumbs. Here these crumbs are entering the soap-conversion tank from the coagulating tank in one of the co-polymer plants of the government rubber reserve company's California synthetic rubber project

Test fleets were maintained by the army, by the Office of Rubber Director (later by the Office of Rubber Reserve) and by numerous private companies in the industry. Information was pooled and cleared through committees, such as the Synthetic Tire committee of the War Production board, and then summarized and released to the industry. Rapid progress was made in the development of satisfactory combinations of the available materials.

By the end of 1944 both civilian and military authorities recognized that the transportation needs of the Allies were being supplied adequately. This achievement rivalled in importance the synthesis of the huge tonnages of rubber in the government plants. As an example of the improvement made in tires resulting from the intensive development program, the following facts had been published: In the 1943 hot weather tests, no group of GR-S truck tires ran more than 5,500 mi., although tires from 9 companies were represented. In a comparable test a year later the average performance (tires from 4 companies) was 10,000 mi., and one group averaged 22,000 mi. In the summer tests of 1945 on 9.90x20 truck tires, the average distance reached 20,000 mi. with a number of individual tires running as far as 35,000 mi. Reports from the Office of Rubber Reserve indicated that GR-S passenger tires in 1945 gave mileages about equal to those of prewar natural rubber tires.

In 1945 German tires were mounted on the government fleet at San Antonio, Tex. These gave less than 20% of the mileage of corresponding sizes of U.S. tires. Constructional details and poor quality of the components, such as rayon, appeared to be the cause of this difference in performance.

Inner tubes of butyl rubber were developed during World War II with air retention seven times that of prewar tubes. Butyl tubes also resisted the growth of tear in punctured regions better than those of natural rubber. It appeared certain in 1946 that there would be a steady demand for this type of rubber in tubes, even after large

supplies of natural rubber became available.

One of the unusual constructions demanded by the military services was the heavy-duty combat tire operable under severe gunfire. Rubber was also designed to perform unusual services like that in the bogie wheels and endless band tracks of military vehicles. The services of supply made extremely heavy demands upon the transport rubber of all movable equipment. In extended operations such as the campaigns in North Africa, Italy and western Europe, as well as in the Pacific theatre, tires, tubes and repair materials were made promptly available in large quantities. These were, of course, mainly of synthetic rubber.

Industrial Products.—The demands of global war upon the world's industrial facilities were well known. Countless miles of rubber fire hose were needed in London, for example, during and after the blitz. Stepping up production meant huge quantities of belting, hose and gasket rubbers. Special compositions, preferably of synthetic rubber, were required wherever fuel or lubricants contacted rubber surfaces as in storage tanks, supply and dispensing hose, hose nozzles, etc. Fortunately, the attention of design engineers and rubber chemists had for a decade before 1940 been directed to the construction merits of Neoprene, the various nitrile rubbers, Thiokol and flexible vinyl plastics. In the stress of war hundreds of uses were found in which the newer synthetics alone could meet the requirements. One or more of the synthetic rubber compositions were found to be superior to those of natural rubber in various properties. These included degree of swelling by gasoline, aromatic solvents, mineral and vegetable oils, acids and water, permeability to gases, improvement in flame resistance and

When small particles of synthetic rubber latex have been coagulated into larger rubber crumbs, the next step in the production of GR-S type synthetic rubber is the filtering and washing of the crumbs. Here the rubber crumb is passing over the Oliver filter and through the pressing rollers, where excess water is removed

Filtered synthetic rubber crumb being conveyed to the disintegrator and drier. The crumb is passed back and forth three times on large continuous belts to evaporate the water in it

in electrical properties, better aging properties under exposure to sunlight, at elevated temperatures and upon storage at room temperature. Because of their superiority for particular uses, these novel synthetic rubbers made an assured market for themselves.

Latex.—Before the war Hevea latex from plantation sources was used in an expanding market. A considerable amount was used in treating tire cords, but large quantities were converted to sponge rubber for mattresses, cushions and arm rests, and to dipped goods of superior quality. By 1940 about 3% of the dry weight solids of rubber converted in the United States industry came from latex. The direct substitution of synthetic rubber latex for natural latex on this large scale proved impractical. Operations in many factories required concentrations of about 60% rubber solids, and a wet coagulum of high film strength with good cohesion, attributes not inherent in all latices of synthetic origin. Systematic trials showed how to make improvements in the various man-made latices used in increasing amounts by the industry to rival the prewar consumption of natural latex. Neoprene and other specialty polymers, like the new vinyl plastic Geon, were also marketed in latex form for expanding uses. Natural latex was thus faced with competition from products which did not exist before 1939. The elegance and cleanliness of processes based upon latex technology offered many advantages to makers of rubber goods.

Postwar Industry in Europe.—The rubber factories of England, France and Belgium suffered considerable damage during the war. Under the command of Gen. Dwight D. Eisenhower, however, operation of the French and Belgian units was resumed early in 1945 to supply tires, tubes and repair materials to the forces of the Allies. Reports from England indicated that despite severe destruction of some factories during the war, the year 1946 marked the resumption of manufacture on a nearly full-scale basis. Meagre reports from the Netherlands also indicated the

resumption of rubber manufacture. GR-S was exported to the European factories on a rather generous scale during 1946.

Trends in the Industry.—As noted above, the attempt to control world markets for natural rubber by the International Rubber Regulation committee, representing 97% of the producing areas, was abruptly terminated by the Japanese invasion of Malaya and the Netherlands Indies in 1942. Although the plan of economic controls had much to commend it, there was inherently an element of shortsightedness in it. Nevertheless, the accumulation of large inventories of rubber by the United States (1940–42) was probably favoured by the fact that there existed a well-integrated International Rubber Regulation committee with whom the Reconstruction Finance corporation, representing U.S. industry, could collaborate. At a later date in 1944, after the gigantic United States synthetic rubber industry had been set going, attempts to include United States representation on the International Rubber Regulation committee were not favoured by the state department. However, a rubber study group was set up, comprising representatives of the United States industry, the Reconstruction Finance corporation and the state department for the purpose of holding periodic discussions with the representatives of the rubber growers, viz., the International Rubber Regulation committee, to arrive at policies that would ensure an adequate supply of rubber in world markets. These discussions concerned the postwar competitive position of GR-S and natural rubber, which was not clarified even by 1946. It was clear, however, that the eventual costs of these two commodities would not be far apart. Costs of production for GR-S on an out-of-pocket basis were reported as low as 11–12 cents a pound, but the average costs had, of course, run much higher than this figure. The export pound price of 18½ cents, established in 1945, for GR-S was also the prevailing price to the

Synthetic rubber blocks, automatically weighed into 75-lb. lots and tested against 1,000 lb. of pressure, coming out of the baler

United States industry. Natural rubber delivered in United States ports was priced at 22½ cents a pound. The differential of four cents was estimated originally to represent roughly the difference in the costs of processing of the two rubbers. The quantities of natural rubber available during the first half of 1946 were smaller than had been anticipated. Political instability in Java and Sumatra, combined with the labour shortage (most severe in Malaya), was largely responsible for this shortage.

By midyear 1946, however, the supplies of natural rubber began to improve.

In the United States the government continued during 1946 as the sole source of rubber for general use by reason of its operation of factories for synthetic rubber, and government ownership of the stockpile of natural rubber. Rubber had for several years been a critical military necessity. Hence, its important place in the national economy made it a focal point of interest in the operation of numerous government agencies. These agencies and representatives of the industry met in Jan. 1946 to formulate a policy concerning the disposition of the government's synthetic rubber plants. Their report, mentioned above, recommended sale of the plants to the industry, the maintenance of a natural rubber stock pile and the continuance of research and development until the government terminated its operation of the synthetic rubber plants. The government had invested more than \$700,000,000 in plants for making butadiene, styrene and GR-S. It had also financed factories for producing rayon, carbon black and tires. This extensive participation by government in the rubber industry was without precedent, and its termination appeared to require the recommendation of the Batt committee, the action of the War Assets administration and the approval of congress. In July 1946 the government announced the sale of the GR-S polymer plant at Louisville, Ky., to the B. F. Goodrich company. This marked the first step in the return of synthetic rubber manufacture to private business.

In spite of the far-reaching changes incident to government participation in the rubber industry during World War II, involving rationing and standardization of product, every effort was made to avoid the imposition of unnecessary controls. Each manufacturer was permitted, as long as he met government specifications, to regulate the composition and construction of his product, provided his methods did not impair the service life of the product. For example, one tire factory used blends of natural and synthetic rubbers, whereas another factory used these components by themselves in individual plies. The integrity of competing units in the industry was recognized and conserved. The practice in Germany was, of course, quite different inasmuch as research, development and the formulation of policies were all formally centralized in a combination of facilities supported by both government and industry.

The reconversion of the rubber industry to civilian goods fabrication in 1946 proceeded much faster than had been estimated in late 1945, thus assuring adequate supplies of tires and tubes by the end of the year. This speedy resumption of normal civilian production by the United States industry was typical of the established pattern which had made the rubber companies noteworthy for their success in perfecting large-scale manufacturing operations. During the war much closer co-operation was required than before, so that competitors got to know each other's methods.

Before World War II, under competitive economy, the performance of tires was improved steadily, in some years

by as much as 10%. Meanwhile, the actual cost per tire mile was, in general, diminished. Rubber goods consumed by industry and agriculture were likewise showing improvements in quality and price stability. This trend on the part of the rubber industry was supported by active programs of research and development, which were not limited to those engaged in the manufacture of rubber products; growers of rubber also had invested extensively in research. Laboratories of the British at Kuala Lumpur in Malaya, and near London, of the Dutch at Buitenzorg, Java, and Delft in the Netherlands and of the French at Paris and at Saigon, French Indo-China, for example, were devoted to studies on natural rubber. Five important manufacturers of rubber in the United States either built or were building impressive new research laboratories in 1946. (See also CHEMISTRY; INDUSTRIAL RESEARCH; PETROLEUM.)

Ruffini, Ernesto

Cardinal Ruffini, (1888–), Italian ecclesiastic, was born at Nantua, France. Ordained in 1910, he studied at Rome, becoming professor of sacred scripture at the Pontifical Propaganda university in 1913. He joined the Sacred Congregation of Seminaries and Universities, becoming secretary of the congregation in 1928. Working under the supervision of Pope Pius XI, he prepared the *Constitution Deus Scientiarum Dominus*, which inaugurated sweeping scholastic reforms in Catholic seminaries and universities. He also personally administered implementation of the constitution for Roman theological, canonical and scriptural universities.

He was named archbishop of Palermo in Oct. 1945 and was serving as prefect of the Sacred Congregation of the Affairs of Religious upon his appointment to the Sacred College of Cardinals in December of that year. He was created and proclaimed a cardinal at the Vatican consistory, Feb. 18, 1946.

Rumania

After 1939 Rumania's frontiers underwent many changes. Bessarabia and northern Bukovina were lost to the soviet union; northern Transylvania to Hungary; southern Dobruja to Bulgaria. On Jan. 1, 1940, Rumania had an area of 113,919 sq.mi. and a population of 19,900,000. On Jan. 1, 1941, Rumania's territory comprised about 74,000 sq.mi. and its population was c. 16,000,000. In 1945 the territory of Transylvania was restored to Rumania. Capital, Bucharest (București). Principal cities: Bucharest (648,162); Jassy (Iasi) (104,471); Galatz (Galati) (102,232); Timișoara (89,872). Religion: mostly Greek Orthodox.

Into the Nazi Maelstrom.—By the opening of 1937, Rumania clearly was following the general central European trend toward authoritarianism and away from Western liberal democracy. The resignation of Nicholas Titulescu as foreign minister (Aug. 29, 1936) had inaugurated a period more sympathetic to Germany and Italy. Rumania, however, still held by the Little Entente and the League of Nations. Her relations with Poland, marked by many exchanges of visits, grew closer. In internal politics, an increasing agitation, directed mainly against Jews but also against the other national minorities, was conducted by the parties of the extreme Right, under the slogan "Rumania for the Rumanians." In Dec. 1937 general elections were held, and following them King Carol II entrusted the government to Octavian Goga, a well-known Transylvanian poet and the leader of the National Christians.

On Dec. 29, 1937, Goga formed a cabinet consisting of members of his own party, with four National Peasants, who were promptly expelled by their own party. Goga began his regime with various anti-Semitic measures on the nazi model, directed chiefly against Jewish doctors, journalists and innkeepers. He also dissolved parliament (which had not met), and ordered new elections for March 1938. King Carol, however, kept foreign policy "independent of domestic policy," and on the old lines of the treaties with France and Poland, the Little and Balkan Ententes, and the League of Nations. On Feb. 10, 1938, amid great economic confusion caused by the government's measures, the king dismissed Goga and appointed a provisional government with the Patriarch of Rumania, Miron Cristea, as premier, and six ex-premiers as ministers without portfolio. In a royal proclamation the king sharply blamed the party system, with which, he said, he had tried to work for eight years. Martial law and censorship were proclaimed, and a series of edicts forbade all state, municipal, etc., employees and all priests to have any contact with politics; dissolved all political parties and associations; and forbade marching in formation, singing political songs, etc. On Feb. 20, 1938, King Carol issued a new constitution, which reduced the number of senators and deputies, raised the life of the chambers from four years to six, offered fuller representa-

tion to peasants, workers, etc., and provided for reform of the civil service. Voting was to be compulsory, suffrage commencing at 30 years (both sexes). Long-established minorities were guaranteed equal rights, and religious toleration was promised.

An open plebiscite on Feb. 24, 1938, resulted in 4,297,851 votes in favour of this constitution and only 5,483 against it; it was promulgated on Feb. 27. On March 30 the cabinet was reconstructed, the ex-premiers and other notabilities being transferred to a council of state. A ministry of national economy and a national economic council were appointed. The National Peasant party protested sharply against the king's *coup*; under the leadership of Julius Maniu it acted as the true and most popular representation of the democratic forces in the country. On the other hand, the authorities in April arrested Corneliu Codreanu, leader of the fascist Iron Guard, renamed the "All for the Fatherland" (*Totul pentru tara*), and nearly 1,000 of his followers who, it was said, were seizing the occasion offered by Germany's occupation of Austria to plot a revolt. On May 27 Codreanu was sentenced to ten years' imprisonment for plotting against the social order, preparation for rebellion, instigation to murder and treasonable relations with foreign powers. Lighter sentences were passed on many of his followers. Later in the year Codreanu and 13 other Iron Guard leaders were shot and killed by their prison guards who maintained that an effort was under way to rescue the terrorists. Members of the party throughout the country were arrested. The anti-Semitic tendency became less pronounced, but Jews resident in the new territories of Rumania on and after Dec. 1, 1918, were required to prove their citizenship, many failing to do so. On Aug. 12 a new statute was issued, abolishing the old historic divisions of Rumania and dividing the country into ten new provinces, grouped round the main rivers. On Dec. 16 a royal decree announced the establishment of a single legal political party, the "National Renaissance Front."

In the Czechoslovak crisis of 1938 Rumania had fully lived up to her international obligations and stood faithfully with her Czechoslovak ally; she consulted with the U.S.S.R., and was believed to have consented to the dispatch of military material from that country to Czechoslovakia. The direct railway line across the northern Carpathians was rapidly expanded. In Oct. 1938, Rumania resisted Poland's endeavours to persuade her to favour the cession of Czechoslovakia's Carpatho-Ukraine to Hungary. Relations with Hungary became severely strained at the time of the new Czech crisis of March 1939, when the Rumanian government refused to participate in the dismemberment of its former ally. But, through the dissolution of Czechoslovakia, Germany had become almost Rumania's neighbour. Troops were called up and remained on the frontier during the summer. By a trade agreement concluded on March 23, 1939 Germany was promised a large share in developing Rumania's mines, forestry, oil wells, etc. and undertook to supply arms and munitions extensively. But subsequent trade agreements with France (March 31) and Britain (May 11) somewhat restored the balance. The British and French guarantees to Rumania (April 11) were received "with satisfaction" by the Rumanian government, at the head of which was Armand Calinescu, who had become prime minister on March 7 following the death of Patriarch Cristea, with Grigore Gafencu as foreign minister.

On Sept. 6, 1939, following the invasion of Poland, Rumania decided to maintain strict neutrality, although the German, and the subsequent soviet advance, which

wiped out of existence her chief ally, made her position very difficult. She showed an increasing tendency to lean on Turkey, with whose help she hoped to weld the Balkans into a "neutral bloc"; but although her neighbours likewise proclaimed neutrality and disclaimed aggressive intentions, both Hungary and Bulgaria were unwilling to join any bloc, instead reviving, ever more openly, their claims on Transylvania and Dobruja respectively. In face of these demands, Rumania declared repeatedly that she would make no territorial concessions.

Prime Minister Calinescu was assassinated in Bucharest on Sept. 21 by a member of the Iron Guard. After some confused changes of cabinet, George Tatarescu, the former liberal leader, formed a new cabinet on Nov. 24 which seemed less remote from the old party alignments, although Gafencu continued as foreign minister. Tatarescu's first task was to give a sharp reply, defending the justice of Rumania's frontiers, to the strong comments which Count Csáky had made in his speech on Hungarian foreign policy on Nov. 21. Relations with Bulgaria remained little more satisfactory, and uneasiness was caused by an article in the *Communist International* of Moscow suggesting that the U.S.S.R. proposed to turn its attention to Rumania when it had finished with Finland. These threats came true in 1940.

At the final opening of parliament on March 7, 1940, King Carol in his speech from the throne stressed Rumania's will to maintain a strict neutrality. But the king was soon forced to proclaim an amnesty for many of the Iron Guard leaders, while the successor of Codreanu, Horia Sima, returned from exile in Germany and resumed the leadership of the party. Prime Minister Tatarescu expressed the hope that, in view of the external danger threatening the existence of the state and the national heritage, all parties would unite in a common defense of the fatherland. This hope proved to be in vain. The fascist party continued its destructive work, and with increased German pressure and the mounting tide of German successes on the western front, Foreign Minister Gafencu resigned on June 1 and was replaced by Ion Gigurtu, an adherent of a pro-axis orientation. On June 27, 1940, the soviet union occupied the provinces of Bessarabia and northern Bukovina, with about 4,000,000 inhabitants and containing Rumania's second and third largest cities, Chisinău or Kishinev with 112,000 and Cernăuți or Czernowitz with 110,000 inhabitants. Rumania was unable to defend her territory against this act of aggression, Germany having apparently acquiesced in the expansion of her then ally Russia. With the complete defeat of France in June 1940, the king was faced by an entirely new balance of power and renounced the British-French guarantee of 1939. The German air force occupied the country under the pretext of protecting the oil fields against a British attack. On July 4, 1940, Ion Gigurtu became prime minister and Horia Sima, the leader of the Iron Guard, became minister of education and "enlightenment." British engineers and oil experts were ordered to leave the country immediately; the largest oil company was taken over by the Rumanian government, which established a monopoly over the exploitation of the oil fields and the export of the oil.

Negotiations with Hungary about Transylvania lasted for several weeks and created much bitterness between the two countries. Budapest claimed the largest part of Transylvania, which until 1918 had formed part of Hungary but was predominantly inhabited by Rumanians and was regarded by them as the most progressive and nationally conscious part. Finally the German and Italian govern-

ments decided the dispute in a way which satisfied Hungary, but left the Rumanian population bitterly hostile. The award of Vienna (Aug. 30, 1940) ceded northern Transylvania with 2,370,000 inhabitants to Hungary.

Less antagonism was caused by the cession of southern Dobruja to Bulgaria, in the treaty of Craiova on Sept. 7, 1940. This quadrilateral plain between the lower Danube and the Black sea had formed part of Bulgaria until 1913 and was inhabited by a Bulgarian majority. In view of the dismemberment of Rumania, Germany guaranteed the frontiers of the state as they emerged after the three territorial cessions. Under this pretext German troops occupied the country.

The Antonescu Regime.—The ensuing unrest and the violent dissatisfaction which the cession of northern Transylvania provoked forced the king to name General Ion Antonescu, a man who leaned upon the Iron Guard for the establishment of his government, as dictator. This move did not, however, ensure orderly administration. King Carol was forced to abdicate on Sept. 6, 1940, and left the country. His son and successor was king only in name; the real power passed into the hands of Antonescu and the Iron Guard, which proceeded to avenge the execution of its former leaders. A large number of prominent Rumanian statesmen, former ministers, generals and high police officers were arrested. An earthquake on Nov. 10, which caused considerable damage though the exact extent was withheld from the public by censorship, aggravated the situation. On Nov. 23 Rumania signed its official adhesion to the Berlin-Rome-Tokyo pact in Vienna. On Nov. 27 the Iron Guard started a week of massacre and terrorization throughout the country. Sixty-four of the arrested dignitaries were executed over the graves of Codreanu and 13 other Iron Guard leaders, who were exhumed and buried a few days later with the greatest pomp.

Relations between Gen. Antonescu and the Iron Guard, however, soon became hostile. By the end of Jan. 1941 a serious fascist revolt broke out under the leadership of some foremost members of the government itself, among them Vice Premier Horia Sima. Ion Codreanu, father of

Territorial changes provided for in the Rumanian peace treaty as recommended to the Council of Foreign Ministers by delegates to the Paris peace conference on Oct. 11, 1946

The Ploesti oil refineries in Rumania were subjected to a concentrated air assault by U.S. Liberator bombers flying at low altitudes on Aug. 1, 1943, severely damaging the principal source of Germany's fuel

the slain Corneliu, also played a prominent part. The minister of the Interior, Gen. Constantin Petrovicescu, likewise was involved; he had been replaced immediately before the outbreak by the military commander of Bucharest, Gen. Demeter Popescu.

The Antonescu dictatorship was accused by the Iron Guard, which embraced most of Rumania's youth, younger officers and many priests, of having sold out the country to the Germans. The fighting between the heavily armed Iron Guardists and government troops lasted for several days. It was accompanied by ferocious pogroms against the Jews, of whom many hundreds were killed. After three days of fighting, Bucharest was again in the hands of the government, but rebel units held out for a short while at Brasov, Ploesti, Arad and Constanta.

While Horia Sima succeeded in escaping, Antonescu, with the help of the Germans, threatened the insurgents with death and tightened his grip on the country. Antonescu formed a new government consisting mainly of high ranking army officers and close personal friends, and announced his intention to develop a closer community of spirit between the axis and Rumania. On Feb. 10, 1941, Great Britain severed diplomatic relations with Rumania in view of the occupation of the country by large German forces; at the beginning of March these forces crossed the Danube into Bulgaria, and on April 6 attacked Yugoslavia and Greece. On March 12 Premier Antonescu held a nation-wide plebiscite. All persons over 21, except Jews, were obliged to vote, no opposition was allowed, and the vote was to be one of approval or disapproval of Antonescu's conduct. Needless to say, an almost unanimous vote of approval was cast. On March 5 Antonescu had seen

Chancellor Hitler and had given Germany full control over Rumania's economic life and foreign policy. Meanwhile the Rumanians complained of the shortage of food in their rich agricultural country as a result of German operations, and the feeling of the people was reported to be so strongly anti-German that there were definite rumours of dissatisfaction on the part of the Germans with Antonescu's regime. Much of the Rumanian dissatisfaction could also be explained by the continued tension with Germany's other friend, Hungary, over Transylvania, whose loss had never been accepted by the Rumanians. How seriously Rumania had been hit by the "new order" could be seen in the fact that while the country had exported, in the first three months of 1940, 412,600 tons of cereals, the exports had sunk in the same period of 1941 to 96,900 tons. In June 1941, a monster trial against the leading Iron Guardists brought heavy punishment to some of the former best known rightist statesmen of Rumania.

War on Russia.—All internal problems, however, receded into the background for a while when Rumania entered the war against the soviet union on the side of Germany (June 22, 1941) to reconquer the provinces ceded to the soviet union in 1940. By the middle of July the formerly Rumanian parts of Bukovina and Bessarabia had been reconquered. But the Rumanian army did not halt at the old frontiers. It had to bear the brunt of the war against the soviet union in southwestern Ukraine, across the Dniester river, and in the siege of Odessa; and

the losses of the Rumanian army were so great that the discontent, silenced for a short while by the military successes, grew again and assumed alarming proportions. The war effort strained the disrupted Rumanian economy so much that war weariness became general and a demand for an end of military operations was heard even in high army circles. Persecution of the Jews in Rumania reached a new height. The territory lying between the Dniester and the Bug rivers, outside the former boundaries of Rumania, was put under Rumanian administration as Transnistria, with the capital in Tiraspol. Antonescu was named marshal on Aug. 23, 1941, in recognition of the Rumanian conquests.

In Sept. 1941 the chief of staff of the Rumanian army, Gen. Mihai Jonescu, was killed on the eastern front. The administrator for Bessarabia and Transnistria, George Alexianu, had to promise radical agrarian reforms to appease the angry peasantry of the newly conquered or reconquered territories. A new plebiscite in Rumania was held on Nov. 9 in which again every citizen had to vote on Rumania's foreign and home policies and had to declare before the vote whether he was going to vote yes or no—whereupon he was handed the corresponding ticket. The German news agency declared beforehand that no one in Rumania doubted that the plebiscite would be an overwhelming demonstration of confidence in Antonescu and his work. But Rumania, in spite of victories and conquests, offered by the end of 1941 a picture of discontent and disorganization. The picture was not brightened by Rumania's declaration of war against the U.S. in Dec. 1941.

In spite of the iron rule of the dictatorship, opposition was strong within Rumania, from two different sources. One was the extremist Rumanian youth, the supporters of the Iron Guard; the other was the democratic peasant party led by Julius Maniu, who insisted upon regaining northern Transylvania and upon a "western orientation" as against Antonescu's expansion eastward. Throughout 1942 many arrests were made. Among those arrested and sentenced were on the one hand young students, on the other hand personalities of high Rumanian society, among them Eugene Titeanu, former minister of propaganda, Radu Lobei, secretary of the former premier Armand Calinescu, and George Deoharl, former deputy mayor of Bucharest. The unrest in the country was increased by the great rise in prices. From Aug. 1939 to Jan. 1942 the increase averaged 300%, and even the domestic foodstuffs rose about 200%. In spite of the great initial military successes, the war grew less and less popular after the hardships of the winter of 1942 and the very heavy sacrifices to which the Rumanian troops were exposed before Stalingrad and in the Caucasus. The war demanded an ever increasing participation of the Rumanian army, much against the expectations of leading Rumanian circles responsible for Rumania's subservience to the axis, and it was believed that the German army command was using Rumanian troops at specially dangerous positions. The vigorous Russian counteroffensive and the British successes in North Africa in the last two months of 1942 increased the feeling of apprehension. In June 1942 the United States struck at Rumania by air for the first time when a small number of Liberator bombers raided the oil fields of Ploesti.

The most important issue of Rumanian foreign policy continued to be her relations with Hungary over Transylvania. Julius Maniu and Constantin Bratianu, leader of the old liberals, signed a memorandum to Marshal Antonescu on Jan. 28, 1942, in which they demanded renewed efforts for the re-incorporation of Transylvania. On Feb.

22 Maniu sent another letter to Vice Premier Mihai Antonescu, and the text of the letter was also made public by leaflets. As a result Mihai Antonescu delivered on March 19 an address in the crowded assembly hall of the Bucharest law faculty where among the cheers and shouts of "give us back Transylvania!" he called northern Transylvania "the cradle of our fatherland" which was subject to a "regime of oppression, humiliation and discrimination." The Rumanian vice premier, who was also acting foreign minister, rejected Hungary's claims of dominating the Danubian basin. Rumania tried a rapprochement with Slovakia and Croatia to check Hungary's aspirations. Only with greatest difficulty did Germany succeed in maintaining the "truce" between Rumania and Hungary, pointing out that a final decision could be taken only after a successful conclusion of World War II.

Disintegration.—In the two following years Rumania's history continued its stormy course. The fast Russian advance through southern Russia in the spring of 1944 brought not only Transnistria again under Russian control, but carried the Russian army and Russian administration back to Bessarabia and northern Bukovina. When the Russian troops crossed the Rumanian border into what they recognized as Rumanian territory, they pledged their intention to respect Rumanian sovereignty, not to interfere with Rumanian internal affairs and social order and not to covet any Rumanian territory.

With the Russian army at the gates of Rumania, Premier Ion Antonescu and Vice Premier Mihai Antonescu tried to make contact with U.S. and British representatives in Turkey and Egypt. The Rumanian will to peace was prompted by continued Allied bombings of Bucharest and of the Ploesti oil fields. By the middle of July 1944 Marshal

Twisted wreckage at a modern cracking unit of the Steua Romana refinery outside Ploesti, largest oil centre in Europe. The Rumanian oil fields and refineries were targets for repeated Allied bombings during April-August 1944

Antonescu realized that Germany was losing the war, and he was reported ready to resign. The German minister to Rumania, Baron Manfred von Killinger, notified Horia Sima, leader of the extremist fascist Iron Guard who had taken refuge in Germany, to be prepared to take over the government. But this threat and all German pressure remained ineffectual; the desire to save Bucharest from destruction by the advancing Russians and the general hatred of the Rumanian armies for Horia Sima prompted a *coup d'état* by King Mihai, who in the night of Aug. 23-24, 1944, arrested Antonescu and his cabinet with the help of loyal generals. The Germans, infuriated by the "betrayal," subjected Bucharest to a heavy air raid. King Mihai ordered his army to cease fire against the forces of the United Nations and declared his willingness to accept unconditional surrender in the name of the nation. He called on the nation immediately to take up the fight by the side of the soviet forces on Rumanian soil against their common enemy, Germany.

The king appointed a military government under Marshal Constantin Sănătescu, consisting of five generals, one admiral and two civilians as ministers with portfolio and representatives of the four big parties as ministers without portfolio. The Germans tried to establish a Rumanian puppet government, but the Russian and Rumanian armies, acting in collaboration under soviet command, soon cleared German troops from the country and reconquered northern Transylvania from Hungary. On Aug. 31 the Russians paraded down the broad Calea Victoriei, Bucharest's main thoroughfare. Baron von Killinger committed suicide. The leader of the Rumanian Communist party, Lucretiu Patrascanu, had secretly met with the king before the *coup d'état* and deliberated with him about its perpetration. The Communists in Rumania supported officially the monarchy and its governments.

The armistice was signed in Moscow on Sept. 12, 1944. Rumania promised to supply at least 12 infantry divisions for the war against Hungary and Germany, to intern enemy civilians, to ensure free Russian troop movements, to repatriate Allied war prisoners, to hand over all German military equipment found in Rumania and to control all enemy alien property. In addition Rumania promised to pay reparations for damages caused to Russia by military operations and occupation. In view of Rumania's help in the war against Germany, Russia declared itself satisfied with the payment of \$300,000,000, to be paid over a period of six years in oil products, grain, timber, ships and various machine equipment. The Rumanian government pledged to return intact all material removed from Russian territory and to restore the lawful rights and interests of the citizens of all Allied nations on Rumanian territory. The Rumanians also promised to disband all fascist organizations and to put all publications, production of plays and films, radio, post, telegraph and telephone under the supervision of the soviet high command. While Rumania renounced definitely Bessarabia and northern Bukovina, the Allies considered the partition of Transylvania as nonexistent and agreed that Transylvania, or at least its major part, should be returned to Rumania.

In the domestic field the Rumanian parties were far from any definite agreement. The most important parties were the National Peasant party under Maniu, the Liberal party under Dinu Brătianu, the Socialist party under Constantin Petrescu and the Communist party under Patrascanu. As these parties could not unite on a com-

promise program, the government continued to be in the hands of the king and his generals, though the second Sănătescu cabinet included mostly civilians. The Russians acted at the beginning very cautiously and did not openly interfere. The jockeying of parties lasted until the beginning of Dec. 1944, when a new Rumanian cabinet was formed, with Gen. Nicolai Rădescu as prime minister and minister of the interior.

General Rădescu had been a staunch adversary of the Germans and of the war against Russia. The national Democratic Front, under the nominal leadership of the vice premier, Peter Groza, but in reality under Communist control, found itself, however, in disagreement with Rădescu. Large scale demonstrations, organized by the Communist party, were held. The hands of the king were forced by the arrival in Bucharest of the Russian vice commissar of foreign affairs, Andrei Vishinsky, who on March 3, 1945, prevailed upon the king to dismiss Rădescu and to appoint a new cabinet under Peter Groza. Rădescu, fearing for his personal safety, took refuge in the British legation.

Groza's Puppet Government.—The new government represented officially a coalition. The prime minister, Peter Groza, was the founder and leader of the Plowman's Front which had split off from the National Democratic Peasant party. Vice premier and minister of foreign affairs was George Tatarescu, formerly an anti-soviet and anti-semitic prime minister (1933-1937) and later a henchman of ex-king Carol II during his attempts at a royal dictatorship. The key ministries were in the hands of Communists: the ministry of the interior commanding the *siguranza*, the dreaded secret police, under Theodor Georgescu; the ministry of justice under Lucretiu Patrascanu; and the ministry of propaganda and press under Petru Constantin. The greatest influence was exercised by Anna Pauker, a veteran woman communist leader. The two most important parties, the National Democratic Peasant and the (conservative) Liberal, were not represented in the government. Much of the communist propaganda was directed against Maniu, the Peasant leader, who was denounced as a "reactionary," and against the western democracies.

Groza's government was strengthened by the restoration of Transylvania, settled by Russia without awaiting the peace conference or any consultation with the Allies. In Transylvania Hungarian inhabitants received wide minority rights. Measures in favour of the poorer peasantry were undertaken as part of a land reform program. Nevertheless, Rumania was faced with a breakdown in its agriculture and with near famine conditions, in spite of its normally great agricultural production. Rumania's industries, especially its important oil wells, were incorporated into the Russian economy.

The growing dissatisfaction in the country, with the absence of democratic liberties and with the existing regime, led King Mihai to appeal in Aug. 1945 to the United States, Russia and Great Britain for the democratization of the regime. But Groza refused to resign. His visit to Moscow the following month strengthened his position. At the beginning of Nov. 1945 popular demonstrations on the king's birthday were suppressed. The Liberal party protested against the abrogation of civil liberties. Even the Social Democrats, who formed part of the coalition, threatened opposition. Their two cabinet members, Labour Minister Lotar Radăceanu and Education Minister Stefan Voitec, supported the Communist demand for the formation of a single worker's party. The overwhelming majority of the Social Democrats and their leader Con-

stantin Titel Petrescu, rejected such a close collaboration and decided to maintain their identity.

The Big Three conference at the end of 1945 in Moscow decided to send representatives of the three powers to Rumania to settle the political crisis by broadening the government through inclusion of democratic elements and by restoring liberty of the press and preparing free elections. The mission was hardly successful. On Jan. 7, 1946, Emil Hatieganu, rector of Cluj university, entered the cabinet as the representative of the National Peasant party, and Mihai Romniceanu as representative of the Liberal

party. Groza promised officially that "the government undertakes to hold free elections as soon as possible, to respect the rights and liberties of citizens, to guarantee freedom of the press, of opinion, of religion, and of assembly, and to guarantee the king's constitutional rights." However, these promises were not honoured. The decisive position of the minister of the interior remained in the hands of Teohari Georgescu, a Communist leader, while the opposition had demanded that the key minis-

tries of the interior and justice be given to nonparty men who would assure freedom from intimidation. Russia objected to any international supervision of elections, thus removing the only guarantee for their relative fairness. Newspapers which expressed views critical of the government were not necessarily suppressed by the government but by the typographical workers who, under order of the Communist unions, refused to print oppositional newspapers and exercised their own censorship over their editorial content. Distribution of the available newspaper by the government was also a factor in "regulating" press and public opinion according to the wishes of the government. Nor was free circulation of "independent" papers assured.

On the basis of the official pledges by the Rumanian government to hold free elections and assure liberty of the press, of speech and assembly, the governments of the United States and Great Britain announced their recognition of the Rumanian government on Feb. 6, 1946. On Feb. 8 the first number of the newspaper of the Liberal party, *Liberalul*, was allowed to be published; but in a signed editorial the liberal leader Constantin Bratianu protested against the fact that in spite of the pledges taken by the government, "public liberties are not yet restored. Journalists receive even now directives as under the regimes of terror, . . . there is not allowed to be read any but extreme leftwing newspapers."

The two representatives of the non-Moscow controlled opposition parties who had been elected to the cabinet in January, were ministers of state without portfolio, spending their time protesting against interference and terrorism directed against their parties. The Social Democrats were brought under Communist control and decided to vote for a single combined Socialist-Communist ticket in the approaching election, thus saving the Communists from a certain defeat at the hands of the electorate. The leaders of the opposition parties charged officially on April 15, 1946, "flagrant breaches with respect to the liberties granted by the Moscow agreement. The clear intention not to co-operate with the opposition is evident by the continual attacks on opposition parties and leaders."

American and British oil companies in Rumania owning about 25% of Rumania's oil expressed fear of the almost complete loss of their invested capital through the forced production and sale of oil at a price far below the production cost. The oil was sold to Russia in fulfillment of armistice obligations. Large quantities of irreplaceable equipment were claimed by the Russians as war booty. Through a network of jointly owned "Sovrom" companies, Russia gained control of all major Rumanian economic and transportation enterprises. Russia enjoyed practically a monopoly in the Rumanian market.

On May 17, 1946, Marshal Antonescu was sentenced to death after a 12-day trial. Twelve other persons were convicted with him, including Mihai Antonescu, the former vice premier, Gen. Constantin Vasiliu, former deputy minister of the interior, and George Alexianu, former governor of Transnistria. They were all executed on June 1, except for Eugene Cristescu, former chief of the Rumanian secret service, Radu Lecca, former commissioner for Jewish affairs, and Gen. Constantin Pantazi, former war minister, whose sentences were commuted to life imprisonment upon the recommendations of the government. (See also FASCISM; WORLD WAR II.)

Runciman of Doxford, 1st Viscount

Viscount Runciman (Walter Runciman) (1870–), British statesman, was born Nov. 19, 1870, at South Shields, England, the eldest son of the first Baron Runciman. Walter Runciman was educated at Cambridge and entered parliament in 1899. He was named president of the board of trade, 1914, but retired from the government in 1916 after a disagreement with David Lloyd George. Runciman, who was not in parliament from 1918 to 1924, was elected in the latter year as M.P. for Swansea West. In 1931 he joined the Liberal-National party and from November of that year until May 1937 (when he was made a viscount), he was again president of the board of trade.

Prime Minister Neville Chamberlain sent Runciman to Prague, Czechoslovakia, in July 1938 to "mediate" the Czechoslovak-Sudeten dispute. Following conferences with leaders of both sides he urged Pres. Eduard Benes to yield to Hitler's Sudeten demands; he recommended im-

mediate cession of the disputed Sudeten areas to Germany, pressed Prague to forbid all anti-German agitation, abolish its alliances with foreign powers and accept guarantees from the major European powers against unprovoked aggression. In Nov. 1938 he was made lord president of the council, a post he held until Sept. 1939. Thereafter he devoted his energies to his many and varied business interests.

Rundstedt, Karl Rudolf Gerd von

Rundstedt (1875–), German army officer, was born Dec. 12, 1875, at Aschersleben, Germany. During World War I he served with German armies in Alsace and Poland. He acquired fame as one of the better German strategists for his operations in the Polish campaign (1939) and in France (1940). He was created a marshal of the reich by Hitler on July 19, 1940. Rundstedt took part in the invasion of the soviet union, inflicted a crushing defeat on Marshal Simeon Budenny in the northern Ukraine but was defeated in turn by Semyon Timoshenko at Rostov in Nov. 1941.

Transferred to France, Rundstedt was made military ruler of all France by Hitler in Nov. 1942. Because of his failure to halt the Allied landings in Normandy, June 1944, he was removed as supreme commander of the wehrmacht on the western front, but was restored to this post in September. Rundstedt's major achievement on that front was the surprise attack against Gen. Dwight D. Eisenhower's forces in the celebrated Ardennes battle in Dec. 1944. Although his armies lacked the force to sustain the operation, it was generally conceded that the attack was brilliantly planned. (Subsequent reports said Hitler had planned and ordered the attack on the Ardennes.) In March 1945 information received by the Allies indicated that Rundstedt had been replaced by Marshal Albert Kesselring.

Rundstedt was captured May 1 by U.S. troops. Testimony given at the Nuernberg trial by Col. Gen. Alfred Jodl, June 5, 1946, said Rundstedt had urged Hitler to sue for peace in July 1944 because the situation of the wehrmacht in France was then hopeless.

Rural Electrification

During the decade 1937–46, more than 2,000,000 of the 6,000,000 farms in the United States received central-station electric service for the first time, and the percentage of electrified farms in the country spurted from less than 15% to more than 52% of the total. By the end of 1946, every U.S. farmer could look forward to the prospect of highline electric service that would bring him the comforts of town and city living and the production methods of modern industry.

In 1935, the stage had been set for great expansion of rural electrification by the launching of a federal program to promote rural electrification. The Rural Electrification administration was established by presidential executive order after congress had included funds for rural electrification in the Emergency Relief Appropriations act of 1935. The agency was given statutory life under the Rural Electrification act of 1936, which originally established a ten-year program; the time limitation was removed by congressional action in 1944.

Under the stimulus of the federal program, methods of power line construction particularly suited to rural areas were developed for the first time in the United States.

Low-cost line-building techniques reduced rural power line construction costs from approximately \$2,000 a mile to less than \$1,000 a mile.

The REA program also stimulated co-operative operation of rural electric systems. The co-operative method of doing business on a nonprofit basis had been so successful in many fields of farmer interest that preference for nonprofit and limited-profit groups as borrowers of REA loan funds was specified in the Rural Electrification act. By 1946 more than 95% of all REA funds had been lent to rural electric co-operatives organized under state laws by rural people who lacked electric service. These co-operatives were controlled and managed by the power consumers they served. Retail rates were based on cost, with allowance for repayment of the government loan.

The full impact of this program began to be felt in 1937. Figures indicated that at the beginning of that year slightly more than 1,000,000 farms had central-station electric service. The subsequent growth of rural electrification, as indicated by the increase in number of electrified farms and in percentage of total U.S. farms electrified, was as follows: 1938, 1,300,000, 19.1%; 1940, 1,870,000, 27.1%; 1941, 2,126,000, 34.1%; 1942, 2,337,000, 38.3%; 1943, 2,454,000, 40.3%; 1944, 2,573,000, 42.2%; 1945, 2,726,000, 44.7%; 1946, 3,107,000, 52.9% (official estimates for June 30 of each year; percentages based upon the 1935, 1940 and 1945 census reports).

Of the 2,100,000 farms electrified between Jan. 1, 1937, and June 30, 1946, about 1,200,000 received service through facilities financed by federal loans. At the end of the 1946 fiscal year, the Rural Electrification administration had allocated more than \$817,000,000 in loan funds to 996 borrowers, of which 918 were co-operatives, 38 were public power districts, 20 were other public bodies and 20 were private utilities, a few of which had borrowed federal funds in the early years of the program. At the close of the 1946 fiscal year, 856 borrowers had in operation about 475,000 mi. of line serving more than 1,549,000 consumers in all states except Connecticut and Rhode Island and in the territories of Alaska and the Virgin Islands. Approximately 80% of the consumers were farms; the rest consisted of nonfarm residences, industrial and commercial enterprises and community institutions in rural areas. Through the end of fiscal 1946, the REA borrowers had paid nearly \$115,000,000 of principal and interest on their loans, of which almost \$20,000,000 represented payments on principal in advance of due dates. In contrast, only \$898,000 owed the government by REA borrowers was overdue 30 days or more.

The example of the REA-financed groups in the rural field stimulated the nation's commercial power companies to a new approach to rural electrification. The utilities began to seek farm customers and, in many cases, to offer them electric service on the terms that had always been available only to city and town customers. By 1946 high connection charges and expensive long-term power contracts for farmers had largely disappeared from the power business. Statistics compiled by the Edison Electric Institute, trade association of the commercial power companies, indicated that as of June 30, 1946, the commercial power companies were serving about 1,900,000 farms, in contrast to a total of only 750,000 farms served on Dec. 31, 1934, shortly before the REA program began. Approximately 900,000 of the utility-served farms were electrified between 1937 and 1946.

Progress in rural electrification was retarded during World War II by restrictions placed on the use of critical materials for new line construction. For a part of the war

period, no power line construction was possible. Later, in recognition of the importance of electrical equipment in producing for war, War Production board regulations were modified so that electric service could be extended to qualified farms for use in war food production and in alleviating rural labour shortages. Although many farmers received electric service under this provision, the rate of farm consumer connections for the nation fell off to about 125,000 a year, less than half the rate that had been maintained from the beginning of 1937 until mid-1942.

This slack construction period provided an opportunity for one of the major rural electrification developments of the decade—the preparation of plans for extending electric service into unelectrified rural communities on an area coverage basis.

With nearly 3,000,000 U.S. farms and an equal number of other rural establishments remaining unelectrified in 1946, rural electric co-operatives in many states had completed plans for bringing service to substantially every unserved farm and other rural residence and establishment in their areas. To facilitate this program, congress in 1944 liberalized the terms of loans made by the Rural Electrification administration. Under the original act, repayment was required over a maximum period of 25 years, with interest ranging from about 2½% to about 2¾%. The 1944 amendment reduced the interest rate to a flat 2% and increased the maximum amortization period to 35 years.

The ability of the rural electric co-operatives to carry out area-wide electrification was also aided by a gradual reduction in wholesale power rates, since the cost of wholesale energy was the largest single item of expense of most co-operatives. Reports of the Rural Electrification administration showed that the average cost of wholesale energy purchased by REA borrowers dropped from 12.1 mills per kw.hr. in 1939 to 8.2 mills in 1945. In large part this drop was the result of an increase in the percentage of total power purchases obtained from publicly-owned power facilities and a decrease in the percentage obtained from commercial suppliers. In 1945, the borrowers paid an average of only 6.6 mills per kw.hr. for power purchased from publicly-owned suppliers, contrasted with 10.1 mills per kw.hr. for power purchased from commercial companies. The authority of the Rural Electrification administration to finance generating facilities, although seldom exercised, had considerable effect in reducing wholesale rates in some areas where no public power facilities existed.

In many sections of the country, rural electric co-operatives and power companies appeared to work amicably side by side, each electrifying farms nearest to its existing lines. In other sections, there were conflicts, stemming chiefly from the co-operatives' insistence on the area coverage approach to rural electrification. Some power companies attempted to "skim the cream," or serve only more populous rural sections that co-operatives had included in their plans and needed to serve in order to carry out area-wide electrification. Many such disputes were brought before state control bodies and even the courts during the decade, with varying results. Some of the leaders of the utility industry proposed that competing co-operatives and utilities serving contiguous territories enter into agreement as to the farms each would electrify, but the Rural Electrification administration refused to approve such agreements on the ground that no farmer could be denied the right to receive electric service under the federal program.

Differences between the federally and privately financed

rural electrification programs were aired in congress in 1945, when several spokesmen for the utility industry appeared in opposition to a bill that would have established a three-year postwar program for the Rural Electrification administration. They took the position that the work of the rural electric co-operatives was essentially finished and that rural electrification should and would be completed in the United States by the commercial power companies. After prolonged hearings, the much-amended bill died in committee, but congress responded to insistent farmer demand for electric service by authorizing REA to lend a total of \$550,000,000 in fiscal 1946 and fiscal 1947—more than had been lent in the previous 10 years of the federal rural electrification program. Loans from this fund, the Rural Electrification administration announced, would enable the rural electric co-operatives to add more than 1,000,000 new consumers to their lines as soon as materials could be obtained. The Edison Electric institute reported in 1945 that its member companies had made plans to electrify 600,000 farms by the end of 1948 if materials became available.

A substantial start on the postwar rural electrification job was made during the 1946 fiscal year. Although line construction materials were almost as scarce as during the war, agencies that had made area coverage plans were able to add new consumers through short extensions to existing lines with minimum use of materials. During the year ending June 30, 1946, rural electric co-operatives extended service to approximately 230,000 new rural consumers—more than in any other year except fiscal 1941. Of this number, about 185,000 were farms. Private companies re-

ported adding approximately 195,000 farms to their lines during the same period. Thus, an estimated total of 380,000 U.S. farms were electrified in fiscal 1946—the largest annual number to that date.

Development of new electrical equipment designed specifically for farm production use became a major activity of many government agencies, agricultural colleges, research institutions and manufacturing establishments during the years between 1937 and 1946. Many a farmer who was content with electric lights and a radio on his electrified farm in 1937 was using, ten years later, a pressure water system, electric refrigeration, electric fences, electric milking machines and milk coolers and an electrically-powered blower to dry his hay in the barn. He could look forward to using electrical home-heating equipment and a variety of other electrical devices still to come. The total value of major electrical equipment in use on the nation's farms in 1943 was estimated at approximately \$600,000,000, nearly two-thirds of which was represented by household appliances. The department of agriculture inter-bureau committee on postwar planning reported in 1944 that electrical farm production equipment would be in greater demand after World War II than ever before. The committee estimated that more than \$4,500,000,000 would be spent by rural consumers during the first 5 postwar years for wiring, plumbing and farm and household electrical equipment.

The increased use of electricity in rural areas after consumers had become acquainted with its many benefits was shown by statistics compiled by the Rural Electrification

The "Farm Equipment Show" staged by the Rural Electrification administration in 1940, toured rural areas of the U.S., where several hundred thousand persons saw demonstrations of labour-saving applications of electricity

administration. In 1945, for instance, it was reported that on REA-financed systems under 3 years old, the average monthly residential consumption was 59 kw.hr., while on systems more than 6 years old the monthly consumption per residential consumer was 97 kw.hr. In some states, average consumption by all REA-served consumers amounted to more than 100 kw.hr. in 1945. One rural electric co-operative in the state of Washington reported an average power consumption by its membership of nearly 250 kw.hr. per consumer per month. REA borrowers distributed nearly 2,200,000,000 kw.hr. of energy during the 1946 fiscal year, an all-time high. This was four times the amount of energy distributed over REA-financed facilities in fiscal 1941, although the number of consumers served only doubled between 1941 and 1946.

During the decade, too, use of electricity in rural industries and in the improvement of rural community facilities increased greatly. More agricultural commodities were processed and needed manufactured articles were produced in small rural sections manned by local labour. Improved schools, churches and health facilities made possible by electric service virtually transformed many rural communities.

So greatly did the rural use of power grow that shortage of power for rural areas became a major concern of groups interested in rural electrification. In 1946, the Rural Electrification administration reported that fewer than half of the energized REA-financed systems were able to supply all the power needed by their consumers. It recommended redesigning of co-operative rural power systems to meet ultimate needs and called upon the power industry for boldness in planning to provide adequate power for rural areas.

Among the scores of technical developments in rural electrification during the decade, one of the most promising was the proposed use of rural power systems for telephone communication. Experimental work in this direction was begun in the early 1940s by the Bell system, the Rural Electrification administration and several interested power companies. The program was suspended during the war, but several trial installations were made in 1945. Two methods of communication were proposed. In one, power wires would actually be used for telephone communication through the use of carrier currents. In the other, telephone and power lines would be strung on the same poles.

(C. R. Wd.)

Great Britain.—In 1936 the national grid of the Central Electricity board had been completed, assuring efficiency in the generation of electricity. In the same year the McGowan committee issued a report on distribution and made recommendations for its reorganization. The government had not in 1946 been able to introduce legislation for this reorganization, but nevertheless considerable progress had been made in rural electrification (which was not state-subsidized in Great Britain) by the supply industry. Some 40,000 mi. of supply lines, constituting the main rural network, had been constructed. Full rural development was envisaged in the postwar period, and the Central Electricity board in 1946 planned an expenditure of £200,000,000 during the following three years for the extension of generating plant.

Between 65% and 70% of the 1,220,000 rural premises, housing some 20% of the total population, had an electricity supply, while the number of connected farms had risen from about 25,000 in 1937 to some 78,000 in 1946, the latter figure representing 27% of the agricultural holdings in England and Wales of 5 ac. and above. The whole of Great Britain was covered by authorized elec-

tricity undertakings, and almost all villages with a population exceeding 250 had electricity. The extension of rural supplies was assisted by the adjustment of the electricity commissioners' regulations, by the introduction of a standard rural overhead line of cheap construction recommended by the Electrical Research association, and in some districts by the use of single-phase supply instead of three-phase.

Superseding the comparative indifference of farmers toward electrification in 1937, there was in 1946 an insistent demand for an electricity supply, stimulated by labour difficulties and increasing costs which made increased mechanization necessary, and by greater agricultural prosperity. Joint liaison committees were set up by agricultural organizations with the Electrical Development association and the Incorporated Association of Electrical Power Companies. In Sept. 1946 it was announced that agreement had been reached between the National Farmers' Union of England and Wales, the Scottish National Farmers' union and the Chamber of Agriculture and electricity supply companies on a 5-year plan to spend £72,000,000 on bringing electricity to 150,000 holdings.

The Hydro-Electric Development (Scotland) act, 1943, established the North of Scotland Hydro-Electric board to provide supplies of electricity to the north and west of Scotland—about two-thirds of the area of that country, having a density of population of only 42 per sq.mi.—not covered by the national grid scheme. This board had already prepared a number of hydroelectric schemes which had been authorized by the electricity commissioners. Constructional work on some had been started. The whole program might cost £100,000,000, and was to provide an estimated total of 300,000,000 units per annum for general use as well as power for the electrochemical and electrometallurgical industries which it was hoped would be established in the area.

In Northern Ireland, substantial progress in rural electrification was made by the Electricity board for Northern Ireland.

Europe.—In France, by 1946, more than 97% of the total of 36,000 rural villages had a supply, and more than 98% of the premises in these villages were connected, although the average annual consumption was 200 kw.hr., which was much smaller than in Great Britain. This degree of electrification had been made possible by substantial government subsidies and state-aided schemes, by loans at low rates of interest to agricultural co-operative societies, by the use of light and cheap overhead lines and by the fact that the electricity supply regulations were less rigorous than in the United Kingdom. Wartime difficulties in obtaining alternative sources of power led to the extensive use of electricity for threshing and for plowing and cultivation in both large-scale farming and market gardening. The other applications of electricity in rural France were very similar to those in Great Britain. Small portable motors were in common use on French farms.

Before World War II, some 80% of German farms were supplied with electricity. During the war, oil engines driving farm machines were replaced by electric motors on a wide scale, and there was in 1946 a relatively greater number of small motors in use for agricultural purposes than in most other countries. Electricity was used for threshing, crop treatment and crop conveying, milking and dairy sterilizing, animal food preparation, water supply and irrigation. Rural electricity distribution was undertaken in some districts by co-operative societies.

The rural districts in Belgium were very widely electrified, but the farms being small, they were not fully equipped with electrical apparatus. In the Netherlands, more than 90% of the rural population had electricity available. In the bulb-growing and market-gardening districts, electric soil warming was used extensively, and some important research had been carried out on the effect of artificial illumination upon plant growth.

Denmark and Switzerland had perhaps the most complete rural electrification in Europe, electrification of rural premises approaching 100% in both cases. In Denmark, development had been greatly assisted by the agricultural co-operative societies, which were an important feature of Danish agriculture, and in some districts small wind-driven generators had been used. In both countries, electricity was used for threshing, milking and other small-power purposes. In Switzerland an ingenious method of applying electricity to the operation of small plowing and cultivating machinery in the field had been developed, and during the war electrically-operated grass driers were introduced, some 50 large driers and 60 small ones being in use in 1946.

In Norway there was considerable interest in electrical plowing and cultivating. In Sweden, where, as in Norway, there is abundant water power, 85% of the 1,000,000 rural premises were already electrified, and a further 10% was scheduled to be connected to the supply by 1950 or 1951. The Swedish government contributed directly to the cost of new connections, and also operated a water power board responsible for generation. Distribution was largely in the hands of local "distribution associations," which took bulk supply from large generating undertakings. Electricity was used for threshing, crop drying and soil warming.

In Italy, there were a number of agricultural co-operative societies which, in addition to distributing electricity, owned and rented electrically operated equipment for threshing and small-power agricultural purposes. Considerable attention had been paid to electric plowing and cultivation; and several machines had been developed and used for the plowing of some thousands of acres.

In the U.S.S.R., a decree was issued in 1939 relating to the expansion of village power plants. In 1940, 92 water power and 60 thermal plants were in operation, but further construction was interrupted by World War II. In 1944 and 1945, some 1,600 plants were built, having a total capacity of more than 70,000 kw. and supplying power to about 700 tractor stations and 2,000 collective farms. Postwar plans provided for the generation, in 33,000 plants, many of them hydroelectric, of 2,000,000 kw. for agriculture and electrifying all machine and tractor stations. The agricultural uses of electricity included water pumping, threshing, drying and grinding, animal food preparation and irrigation and electrically operated plowing was planned.

For the rehabilitation of Greece after World War II, a 20-year national water power plan had been prepared, involving 16 hydroelectric stations connected by a high-voltage transmission network. Although no detailed plans had yet been made for rural electrification, such a network would obviously pave the way.

In Eire, the Electricity Supply board was authorized to carry out a rural electrification scheme on a national scale at a cost of some £40,000,000. The outline of the organization for this scheme had already been drawn up. (See ELECTRICAL INDUSTRIES; PUBLIC UTILITIES; TENNESSEE VAL-

LEY AUTHORITY; WATER POWER.)

Russian Literature

Contemporary themes dominated soviet literature during the decade 1937-46. The generation which grew up after 1917 had taken its place in life, and the traits of character formed in these years acquired definite shape. The writers' attention was concentrated on the delineation of the ordinary soviet people who typified the contemporary soviet character. Great interest was aroused by *Tanker Derbent*, written by Yuri Krymov, who was born in 1908 and died in battle in 1941. This was the first attempt at the portrayal of the Stakhanovite movement, a new socialist attitude to work which was defined by Stalin as a "matter of honour, glory, valour and heroism." These traits are seen in Konstantin Simonov's play *A Lad from our Town*, in the poetry of the old Kazakh Jamboul (1846-1945), in that of the Armenian poet Avetik Isaakian, the Georgian poet Galaktion Tabidze, the Byelorussian Yanko Kupalo (1882-1942), the Ukrainian Pavel Tychina, the Russian A. Surkov and others. The individualistic poetry of Boris Pasternak, who confined himself to a personal theme remote from the common interests of the people and later took up the translation of Shakespeare, stood apart.

So stirred were the soviet writers by construction work of peacetime during the early years of the decade that the national defense theme in itself did not evoke a response of great moment except for isolated books such as Peter Pavlenko's *In the East* and Nicholas Panov's poem *Tank Commander*. Soviet literature was preparing for the struggle to come. A large part was played in this by the historical genre—for example, *Sevastopol* by Sergeyev-Tsenski, writer of the older generation born in 1863, and *Suvorov*, a historic poem by Konstantin Simonov. Works on the civil war were of special importance. In 1941 Alexei Tolstoy (1873-1945) completed his trilogy *The Road to Calvary* which he began in 1921. This novel, which traced the way by which the Russian intelligentsia found closer contact with the people in the epoch of the revolution and merged with them, was one of the most significant books of the period. Equally important was the role of Mikhail Sholokhov's novel *And Quiet Flows the Don*. The writer spent 14 years on it, completing it in 1940. It is an immense canvas of the Don Cossacks during the revolution. The philosophical problem that it raised was the tragedy of man torn away and isolated from his

people. Nicholas Pogodin's plays, *Kremlin Chimes* and *A Man with a Gun*, in which Vladimir Lenin and Joseph Stalin appear, aroused much interest.

The German invasion of the soviet union confronted writers with new and responsible tasks. More than 800 of the 3,500 soviet writers went to the front and more than 300 were awarded military decorations; 242 were killed in active service. Among these were Eugene Petrov (1903-1942), A. Gaydar (1904-1941) and V. Stavski (1900-1943).

At the beginning of World War II more "operative" genres—lyrical verse, short feature articles and good journalism on questions of special interest—were favoured. Articles by Alexei Tolstoy and Ilya Ehrenburg were extremely popular. Outstanding war correspondents were Konstantin Simonov, who wrote the series *From the Black Sea to the Barents Sea*, Vassili Grossman (*Stalingrad Notes*) and Boris Gorbатов (*Tales of a Soldier's Soul*). At the same time the war story was popular; this of course gave more scope for artistic invention than an ordinary feature story. Nikolai Tikhonov, who remained in Leningrad throughout the blockade, described it in a book *Traits of the Soviet Citizen*; L. Sobolev pictured various aspects of navy life in his *Sea Soul*.

Stories and feature articles appeared in the papers alongside important information. By the beginning of 1942 a somewhat larger genre gained a footing; stories endeavoured to give a more general picture of the war. *Immortal People*, Grossman's war novel, traced the steps by which the soviet army grew stronger in the test of war; Gorbatov's *The Unconquered* conveyed the staunchness of the spirit of the soviet people in the territory occupied by the Germans; Mikhail Sholokhov's *Science of Hatred* and Wanda Wasilewska's *Rainbow* gave a forceful picture of atrocities of the fascists.

A. Bel developed the genre of the documentary story; his *Eighth of December*, *The Volokholamsk Highway*, *Panfilov's Men* and *On the Boundary Line* were about the days of the defense of Moscow and the beginning of the end for the Germans outside Moscow in Dec. 1941. Of great importance, too, was Simonov's *Days and Nights*, in which the author tried to convey the immensity of the Stalingrad battles and the courage of the soviet soldiers. But perhaps the most prominent place among war stories was taken by Alexander Fadeyev's novel *Young Guard*. The narrative was written around actual events. It was the history of the underground organization of the soviet youth formed for the most part from schoolchildren in the Donbas colliery town of Krasnodon in the German rear. For some months this organization harassed the fascists but eventually it was discovered, the members were caught and put to death. Fadeyev raised the narrative to a high literary level, treated the documentary material with creative talent portraying the people who actually existed as characters that are typical and throwing into relief the most essential traits of soviet youth. The underlying idea was that the soviet people considered themselves representatives of the nation and that this first and foremost determined their behaviour.

The historical genre continued to develop during World War II. The last part of the best soviet historical novel *Peter the First* was left unfinished by Alexei Tolstoy's death. *Navoi*, a novel by the Uzbek poet and scholar Aini Aibek, was devoted to the life of Alisher Navoi, the founder of the Uzbek literature of the 15th century. V. Shishkov, a representative of the older generation, wrote *Yemelyan Pugachev*, a novel of the peasant rising of the 18th century. A. Stepanov's monumental novel *Port Arthur* aroused wide interest.

Outstanding among volumes of lyrical verse which number several score was A. Surkov's *Songs of a Wrathful Heart*. There was a marked tendency to broad synthesis, to the imagery of the artistic magnitude characteristic of soviet literature. This was determined by the breadth of outlook and wealth of social experience of soviet writers, their many-sided and direct participation in the life of the country. The long poem was one of the most widespread poetic genres during World War II.

Beginning with Nikolay Tikhonov's romantic poem *Kirov Is With Us*, which was published in 1941 and dedicated to besieged Leningrad, soviet poets published many poems on widely diversified themes. A realistic and stirring picture of Leningrad was given by the women who took part in its defense, for example, Vera Inber, who wrote *Pulkovo Meridian* and Z. Shishova, who wrote *Blockade*. In a place apart were the poems constructed on the basis of documentary material that passed through the keenly lyrical perception of the poet: Pavel Antokolski's poem *Son*, dedicated to the memory of his own son who was killed in the war, was an expression of personal grief merging in the general flood of national feeling and finding its loftiest expression in it; Margarita Aliger's long poem *Zoya* was on the heroic young girl partisan Zoya Kosmodemyanskaya who was tortured and hanged by the Germans.

The most prominent place among war poems was taken by Alexander Tvardovski's *Vassili Tyorkin*. This was an attempt to depict the Russian soldier, who bore simply and with optimism the hardships of war. The poet, who made wide use of colloquial Russian, drew most varied pictures—everyday and tragic—of the life of the soviet army at the front. He made a thorough study of his subject. He succeeded in creating work of high literary significance that acquired instant popularity, especially in the army.

Soviet wartime drama presented a less rich picture than did prose and poetry; nevertheless it had a number of plays that attracted wide attention and assumed a part of importance at the time. One of the first plays to be published was *The Russian People* by Simonov, fertile and versatile prose writer, poet and journalist. Against the background of a Russian garrison in a small town Simonov showed the greatness of a soviet soldier's soul, his readiness to sacrifice and do brave deeds for his country's sake. The theme of rallying the Russian people at the moment of danger was chosen by Leonid Leonov for his play *The Invasion*. Alexander Korneychuk's play *The Front* aroused wide interest. On the one hand it showed how the soviet army commanders mastered the new machinery and technique of warfare while the war was going on and on the other hand it was unsparing in its exposure and condemnation of routine methods and those who did not understand the new experience.

Folklore—the creative literature of the people handed down by word of mouth—received a new impetus and was given an unusually wide scope during World War II. It responded in a variety of ways to the events of the epoch. Songs, tales, proverbs and axioms made up in the soviet army, among the partisans, among the children and so on expressed the soviet people's patriotic inspiration and faith in their own powers.

(L. Tv.)

A special resolution of the central committee of the Communist party denounced in Aug. 1946 the work of two Leningrad reviews (*Zvezda* and *Leningrad*), accusing them of sponsoring "anti-soviet writers." The once popular humorist Mikhail Zoshchenko and the well-known

poetess Anna Akhmatova were singled out for a particularly virulent attack. Zoshchenko was charged with showing "an unpatriotic attitude during the war" and with lampooning soviet society in *The Adventures of an Ape*. Akhmatova's poetry was proclaimed "empty" and "imbued with bourgeois mentality." A more general charge of "servility to modern western bourgeois civilization" was laid at the door of the Leningrad reviews; they were accused of "poisoning the mind of soviet youth." After listening to a report from Andrey A. Zhdanov, the official head of the Leningrad communist organization, the Leningrad writers hastened "to assure comrade Stalin that they would be able to overcome in a short time these major shortcomings." This episode was but part of a general tightening-up of the ideological party line which came as a reaction after wartime "laxity": Moscow theatres were severely rebuked for including in their repertoires "decadent" bourgeois plays by Somerset Maugham, Sir Arthur Pinero and others, and the composer Shostakovich was taken to task for his *Ninth Symphony*, proclaimed "a formalistic trifle."

Nikolay Tikhonov was dismissed from the post of chairman of the Union of Soviet Writers and replaced by a "collective."

Rutledge, Wiley Blount, Jr.

Rutledge (1894–), U.S. jurist, was born July 20, 1894, in Cloverport, Ky. He received his B.A. degree from the University of Wisconsin in 1914, and his law degree from the University of Colorado in 1922. Admitted to the Colorado bar in 1922, he practised in Boulder. Four years later he joined the University of Washington as professor of law, remaining at that institution until 1935, when he became professor of law and dean of the law college at the University of Iowa. He left the latter school upon his nomination in April 1939 as associate justice to the U.S. court of appeals for the District of Columbia; he entered his new duties the following month. On Jan. 11, 1943, Pres. Roosevelt named him associate justice to fill the vacancy left in the U.S. supreme court by the resignation of Justice James F. Byrnes. He was sworn in Feb. 15, 1943. Only 48 years old at the time, Justice Rutledge was the second youngest member of the court (Justice William O. Douglas, the youngest member, was then 44). Justice Rutledge entered dissents in the supreme court ruling (Feb. 4, 1946) that upheld the legality of the U.S. military tribunal which sentenced Lt. Gen. Tomoyuki Yamashita and also in the ruling (Feb. 11, 1946) denying clemency to Gen. Masaharu Homma.

Ryder, Charles Wolcott

Ryder (1892–), U.S. army officer, was born Jan. 16, 1892, in Topeka, Kansas. A graduate of the U.S. Military academy at West Point, (1915), he was commissioned a second lieutenant. During World War I he fought on the western front, was cited for heroism and received a number of decorations. After the war he was stationed in China and served for a while in military intelligence. One of the commanders of the U.S. armies that landed in French North Africa on Nov. 8, 1942, Maj. Gen. Ryder led the force that landed in Algiers and he negotiated surrender of the French garrison there.

After the occupation of Morocco and Algeria Gen. Ryder's armies were placed under the command of Gen. K.A.N. Anderson of the British 1st army on Feb. 11, 1943. Ryder himself commanded the 34th national guard division in the drive on Bizerte.

Allied headquarters in Italy announced July 29, 1944, the transfer of Ryder from the Italian theatre of war to new duties in the U.S.

Rye

World rye production was estimated by the United States department of agriculture at about 1,000,000,000 bu. in 1937. Germany produced about one-third of this total and half of the crop of Europe. Rye production declined steadily during the war period although it was the chief bread grain in several European countries and in parts of the soviet union. The supplies were so small that it could not be substituted for wheat, and the price was also higher in the United States.

Rye was the one U.S. grain crop which did not play an important role during World War II; it ended the decade 1937–46 with a decline to the level of pre-World War I. Rye had been grown on about 3,500,000 ac. after 1914 except for a brief period of expansion in 1919, when acreage increased to more than 7,000,000 ac. and again in 1922, when the acreage was 6,757,000 ac. and a record high yield of 14.9 bu. per ac. returned a crop of 100,986,000 bu., the all-time record. In 1937 the acreage harvested for grain was back at 3,846,000 ac. and the crop to 49,830,000 bu. The decline in production continued, except for 1942, when again a yield of 14.9 bu. per ac. brought the crop up to 57,673,000 bu., to a low point of 25,500,000 bu. in 1944. Only about half of the rye acreage was harvested for grain: 56% in 1945 and 52% in 1944. Yields were low in 1933–34, about 8.5 bu. per ac. and, except in 1942, at about the prewar average through the decade 1937–46. After the beginning of the century there had been only five rye crops smaller than that of 1945.

U.S. rye prices declined in 1938 but began to recover in 1939 and advanced steadily until 1946. The use of rye during the decade was principally for feed. The 1944 crop,

*Preliminary estimate.

stocks and imports, totalled about 55,000,000 bu., distributed as follows: food, 9,100,000 bu.; feed, 15,800,000 bu.; seed, 6,200,000 bu.; industrial uses, 10,300,000 bu.; and exports, 3,200,000 bu. Between the two world wars rye exports rose to more than 50,000,000 bu. (in 1922 and 1924), but then declined and a balance of imports was required after 1933. The decline in production of rye was because of the fact that it could not compete with wheat in income per acre, and the crop was grown as a supplement to other grains.

There were speculative flurries in the rye markets in 1945 and 1946.

During Feb., March and April 1946 the farm price of rye was higher than the price of wheat. (J. C. Ms.)

St. Louis

At the start of the decade 1937-46 St. Louis was pulling itself out of the depression. War in Europe in 1939 accelerated recovery and started a boom. The six most momentous years since the Civil War followed. The city was destined to play an active part in the nation's war effort because of its access to raw materials, fuel and labour. By April 1941, St. Louis already had received direct defense contracts totaling \$250,000,000 and construction was soon to be started on an \$80,000,000 small arms ammunition plant, largest of its kind in the world, and a \$60,000,000 T.N.T. plant. As war threatened the United States, new plants and expansions mushroomed. Before the close of the war, \$447,000,000 was spent on such new facilities. Historic Jefferson barracks, 120 years old, was a beehive of activity, and other major military establishments were springing up in and near St. Louis. Men and women from the St. Louis area were swelling the service forces by an eventual 125,000. St. Louis was the nation's first city to reach its quota in one of the early war loans. By the beginning of 1944 industrial output of the St. Louis area was double normal production. War contracts in that year equalled the total for the previous three and one-half years. Employment increased from 533,019 in 1940 to 662,600. By the close of the war in 1945 the St. Louis area had received government contracts totalling \$2,500,000,000.

Before the end of hostilities St. Louis was preparing for reconversion and the postwar period. On Aug. 1, 1944,

voters approved a \$43,427,000 bond issue for postwar public improvements. To this was added almost \$20,000,000 already on hand. For improvement of the water system \$19,000,000 would be spent; for improvement of airport facilities, \$14,000,000.

The war made the city air-minded. Under way in 1946 was a two-year program to triple the size and improve the facilities of Lambert-St. Louis municipal airport at a cost of \$10,000,000. The city was also in the process of acquiring a 4,000-acre site for a second municipal airfield costing \$15,000,000.

The voters on Aug. 6, 1946, approved another bond issue—\$4,000,000—to provide for a rubbish and ash collection service.

Many things happened in 1946, the end of an eventful decade. Agreements were reached to bring natural gas to the city within a year. For many years consumers had been furnished a mixture of natural and artificial gas. The Veterans' administration announced intention to give the city veterans' hospitalization buildings costing \$22,000,000. Jefferson barracks, historic frontier military post established in 1826, was deactivated and turned into housing for war veterans.

Politically, St. Louis changed from Democratic to Republican in the decade. An eight-year Democratic rule was ended April 2, 1941, when Republican William Dee Becker was elected over Mayor Bernard F. Dickmann, Democrat seeking a third consecutive term. But tragedy overtook Mayor Becker. During an aircraft demonstration before 5,000 spectators at the municipal airport on Aug. 1, 1943, a towed glider lost a wing and crashed. Among the ten occupants killed was Becker. He was succeeded by Aloys P. Kaufmann, who three months earlier had been elected president of the board of aldermen. Virtually unknown politically when he succeeded Becker, Kaufmann was elected to the unexpired term in Nov. 1944, by the biggest mayoralty margin since 1900, and was carried to a second term by a record majority of 108,654 to 54,512 on April 3, 1945. One of the city's proudest accomplishments was the elimination of the smoke nuisance, for 50 years a bane to St. Louis. It was effected chiefly by a drastic ordinance which, with other strong regulations, prohibited use of coal having less than 23% volatile matter in any except smoke-reducing equipment.

In Sept. 1942, civil service in city government was instituted.

Charter amendments required election of aldermen by ward instead of at large and equalized in size and population the 28 wards of the city.

To keep the city's financial head above water, a debated step was taken Aug. 1, 1946. A city income tax of one-fourth of 1% on gross earnings of individuals and net profits of businesses went into effect. The tax was estimated to yield \$4,000,000 annually, with half going to provide salary increases for the 8,000 municipal employees.

The prosperity of the latter half of the decade was exemplified by banking figures. At the beginning of 1937 there were 34 banks in the city of St. Louis with total resources of \$763,722,031, deposits of \$693,017,101 and capital and surplus amounting to \$63,004,759. Near the end of the decade there were 31 banks with resources totalling \$1,595,031,327, deposits of \$1,499,749,876 and capital, surplus and undivided profits amounting to \$80,331,891.

Throughout the period the municipal government maintained a sound financial position. The annual deficit grew smaller until in 1943 the budget was balanced for the first

time since 1928, and the fiscal year ended with a surplus of \$513,174. This surplus grew until 1945 when it reached \$3,145,275, then, because of increasing costs, began going downward sharply. The municipal debt, including bonds outstanding and those authorized but not issued, totalled \$87,391,000 in 1946—\$34,953,877 under the debt limitation.

The assessed value of real and personal property rose from \$989,297,745 in 1937 to \$1,053,130,974 in 1945. In that period the assessed value of railroads and other public utilities dropped from \$48,321,344 to \$47,171,689.

After administering the archdiocese of St. Louis for 42 years, Archbishop John J. Glennon, at the age of 83, was appointed to the College of Cardinals by Pope Pius XII on Dec. 23, 1945. While on his way home from Rome, Cardinal Glennon died in his native Eire.

A notable addition to the city's monuments in 1940 was Carl Milles's sculptural group, "The Meeting of the Waters," in the plaza facing the Union station.

By 1940, the population of St. Louis was 816,048, but because its boundaries, enclosing 61 populated miles, had not expanded since 1876, more than 500,000 persons lived in the area closely surrounding the city limits. (The 1940 census showed the St. Louis area pop. to be 1,367,977.)

Sakhalin

Sakhalin Island, in the north Pacific Ocean, became in its entirety a part of the territory of the soviet union after World War II. At the Yalta conference, Feb. 11, 1945, the president of the United States and the prime minister of Great Britain secretly agreed to the reunion with Russia of southern Sakhalin (a Japanese possession since 1905) and to other territorial arrangements in return for a soviet undertaking to declare war against Japan within three months after Germany's surrender. Southern Sakhalin was subsequently shelled by U.S. warships, and a U.S. naval party landed on it in July 1945, but the island was not subjected to heavy bombing. Soviet troops invaded southern Sakhalin early in Aug. 1945, and a soviet communiqué announced on Aug. 28 that the clearing of Japanese troops had been completed. Russian colonization of northern Sakhalin had gone on during the war.

Japanese coal and oil concessions in the soviet territory of northern Sakhalin, granted in 1925, were a source of friction between the Japanese and soviet governments un-

til the signature of the Moscow protocol of March 30, 1944, under which the concessions were cancelled and all property of the Japanese concessionaires was transferred to the U.S.S.R. in return for a payment of 5,000,000 roubles and a soviet promise to sell Japan 50,000 metric tons of oil annually during a five-year period after the conclusion of World War II. The most serious diplomatic crisis concerning these concessions occurred in 1939, when soviet authorities in northern Sakhalin levied fines against the Japanese concessionaires, who complained that the U.S.S.R. was applying pressure to restrict production from their concessions. The accompanying strike was settled only after difficult negotiations between Japanese concessionaires and soviet trade unions involved. (G. M. R. D.)

Salazar, Antonio de Oliveira

Salazar (1889–), Portuguese statesman, was born April 28, 1889, at Santa Comba Dão (Coimbra). He joined the Coimbra university faculty in 1916 as professor of economics and was finance minister for a week in the government of Pres. Antonio de Fragosa Carmona shortly after the revolution in 1926. In April 1928 he returned to the finance ministry. In July 1932 Salazar became premier; the following year (March 1933), a new corporative constitution was adopted, and the government became a dictatorship run by Carmona and Salazar.

In 1936 Salazar assumed the portfolios of war and foreign affairs, but in 1944 he yielded the war ministry. On May 18, 1945, in a speech before the national assembly justifying Portuguese neutrality in World War II, Salazar declared "It cannot be disputed that it served a positive interest of the Allied nations for us not to have become involved in the conflict." He also stressed the desire of his government to collaborate in the postwar world and affirmed the truly democratic character of his regime. But in a campaign speech of Nov. 9, 1945, he denounced democracy as a "hopeless system."

Meanwhile, Salazar had permitted the creation of political parties other than his own, that of the National Union, and announced national elections, the first in 20 years, for Nov. 18, 1945. The opposition, however, boycotted the elections, charging that their candidates had to secure "approval" by the National Union before they could be listed. The National Union won the elections.

Saliège, Jules-Geraud

Cardinal Saliège (1870–), French prelate, was born Feb. 24, 1870, at Mauriac, France. Ordained in 1895, he later taught mathematics and theology and was cited for his service as an army chaplain during World War I. He was consecrated bishop in 1926 and elevated to the post of archbishop of Toulouse in 1928.

Archbishop Saliège distinguished himself during World War II by issuing a pastoral letter, read in all churches of his diocese, denouncing racial persecution. This action, which came in the midst of a nazi-ordered manhunt for Jews, displeased the German occupation authorities and he was placed under arrest, only to be released later because of his advanced age and ill health. He was permitted to remain in his archbishopric.

He was named to the Sacred College of Cardinals, Dec. 23, 1945, and was created and proclaimed a cardinal on Feb. 18, 1946. As illness prevented his personal attendance at the Rome consistorial ceremonies in February, he was given his red hat at a private Vatican consistory on May 17, 1946.

Salt

The production of salt is one of the world's most widely distributed mineral industries, as it is one of the oldest; man has always required salt, for food if for nothing else. Almost every country has some output, and production has been recorded in some fourscore of them. Known output in 1937 was in excess of 33,000,000 short tons, in amounts varying with the population and the industrial activity of the country in question. Heavily populated countries like India and China required from 1,500,000 to 3,000,000 tons for food uses only; on the other hand, a heavily industrialized country like the United States required several times as much salt for industrial uses as was consumed in food. Hence, nearly four-fifths of the world output continued to come from only eight countries, the five with the greatest industrial development (United States, Germany, Great Britain, France and Italy) and the three with the largest population (China, India and the Japanese empire), all with outputs in excess of 1,000,000 tons. Production data during World War II were too scattered to permit any estimates of total output, but the number of countries showing increases, up to double or more between 1937 and 1945, seemed sufficient to offset any likely decreases, leaving a margin of increase.

The United States continued to be the world's largest producer and consumer of salt, with 25% of the world total in 1937; since the United States output more than doubled during the following decade, the percentage was

probably greater in 1946.

The trend of U.S. output and consumption is shown in the accompanying table.

Uses.—As indicated in the table, chemicals absorbed over two-thirds of the total salt output; of the total chemical uses, soda ash alone accounted for nearly half the total consumption, while chlorine and chlorine compounds (other than salt itself) took one-sixth, with around five per cent for other chemicals. The uses of salt in connection with foods—their production, preservation and use—though the most familiar to the average person, accounted for only about one-fifth of the consumption, while uses connected with personal health, safety, comfort or convenience absorbed about 4% of the total.

The industrial phases of the war program required large amounts of salt for the production of soda ash, chlorine, while stock feeding and food processing also were deeply involved in the war food program. Among the many lesser uses in which salt or one of its derivatives contributed to the war program were water purification, treating roads and airfield runways, making smoke screens and smoke bombs, water- and mildew-proofing compounds, parachutes, high-octane gasoline, the processing of textiles, the production of synthetic rubber and other rubberlike materials, the production of magnesium metal, DDT, sulfa drugs, vitamins and many others. While some of these uses were merely adaptations of established commercial and industrial applications, others were new developments, confined to military needs for the time being, but many later adapted to peacetime civilian uses.

(G. A. Ro.)

Salvador, El

A republic on the west coast of Central America, the only one without a Caribbean littoral, El Salvador is the smallest Central American and the second smallest Latin-American state (area, 13,176 sq.mi.) but the most densely populated mainland republic in the hemisphere. The population was estimated in 1943 at 1,896,168; earlier official estimates included the following: 1939, 1,744,535; 1940, 1,787,930; 1942, 1,862,980. The density by an official 1942 estimate was 141.39 per sq.mi., with only one of the 14 territorial departments falling below 100 per sq.mi in density. Racial distribution was approximately 80% mestizo (including white) and 19% Indian. Some three-fifths of the pop. was rural, two-fifths urban. The capital is San Salvador (1943 est. pop., 107,813); other important urban centres are Santa Ana (46,806), Nueva San Salvador (formerly Santa Tecla; 24,016), San Miguel (18,945), Sonsonate (17,320), Cojutepeque (15,095), Ahuachapán (13,636), San Vicente (13,330), Zacatecoluca (10,822), and Suchitoto (10,350). Presidents during the decade 1937–46 were Gen. Maximiliano Hernández Martínez (1931–May 8, 1944); Gen. Andrés Ignacio Menéndez (May 9, 1944–Oct. 21, 1944); Col. Osmin Aguirre y Salinas (Oct. 21, 1944–March 1, 1945); Gen. Salvador Castañeda Castro, after the latter date.

(X.)

Four Constitutions.—During the decade 1937–46, El Salvador had four constitutions: the first had been in force since 1886 and was without doubt the one most widely approved by the people of El Salvador because of its liberal and democratic tendencies; the second was promulgated in 1939 and had marked dictatorial tendencies; the third, in 1944, was meant only to perfect and give a certain air of legality to even more absolutist tendencies, and retained almost nothing of the constitution of 1886; the fourth, in force at the end of the decade, was essentially modelled on the liberal-democratic charter of

1886. The ten years were in reality a period of difficulties and of undeniable historical significance for the country, in which its whole political, social and economic structure was subject to intense disturbances; it was a period of constant change, which agitated public opinion and gave strong evidence of the civic spirit of the Salvadorean people, and its old and ineradicable tradition of national unity and democracy.

The liberal and democratic tradition of the country, which had its historical roots in its Spanish origin and in its revolution against the kings of Spain at the beginning of the 19th century, found its expression in the constitution of 1886.

But toward the end of 1939, the strong desire of the government of President Martínez to introduce important reforms in that constitution became evident. A constitutional assembly, convoked in a plausible way, held its sessions under a state of siege at the end of 1938; thus recourse was taken to means often before used in Latin-American countries, that is, to call open meetings or plebiscites which, being held under government control, necessarily produced the desired results. A constitution resulted which brought about changes of a definitely totalitarian character. Public liberty was restricted; municipal autonomy, which had been one of the oldest and most cherished democratic traditions of the country, was destroyed. The principle that the president of the republic could not be re-elected, also one of the traditional basic elements of Salvadorean democracy, was annulled to all intents and purposes.

The constitution, promulgated and put in force at the beginning of 1939, was tolerated, although the vast majority of the people seemed opposed to it; it remained in force with a certain amount of public approval, as it made

some just and basic reforms with regard to the family and the financial administration of the country.

At the end of 1943, the government created new problems and activities designed to introduce reforms in the constitution, with the ostensible intention of prolonging the functions of the chief of state for a new period of time; it also intended—at least so it said—to introduce special legislation in the economic sphere with respect to the property of axis subjects; the country had declared war on those states in Dec. 1941. The constitutional assembly again met under a state of siege, and when the new measures were promulgated the country realized that they meant the creation of a totalitarian state in which all rights and privileges—religion, family, franchise, municipal administration, property, freedom of thought—were made subject to the decision of the chief of state, who was vested under the guise of some spurious reasons with absolute powers and rights. As soon as the country realized this, military forces of the garrison in the capital, including especially air force contingents and the First and Second Infantry Regiments, rose in open rebellion on the afternoon of April 2, 1944, Palm Sunday.

Revolt of 1944.—Fighting went on for more than 70 hours in the city and its surroundings, until the uprising was more or less defeated by noon of Tuesday, April 4, when white flags went up in some of the rebel positions. Summary military tribunals were set up which condemned to death leaders, officers and civilians considered guilty. More than ten of these were executed, and the country was outraged by these proceedings. A wave of panic and indignation swept the nation; further executions took place at short intervals, sowing anguish and terror in the hearts of Salvadoreans, as the arrests of citizens were going on all the time, sometimes with no more reason than slight suspicion. The country lived through days of anxiety and emotion, and discontent spread among all social classes, even including those circles that could be considered partial to the government. Underground movements began to unite their efforts, and the national spirit soon forged a formidable front of unity against this state of affairs. Quickly their efforts rose to the surface, manifesting themselves in passive resistance by the medical profession, aided by students and workers; the movement rapidly became a general one, paralyzing transportation, trade, the supply of electricity and food, etc. A general resistance committee was set up, which acted rapidly, and was finally invited to present its views. Only one outcome was possible, and a government crisis began which culminated in the abdication of President Maximiliano Hernández Martínez; congress accepted it on May 9, 1944, and chose General Andrés Bello Menéndez to succeed him.

When the national legislative and constituent assembly met again after President Castañeda's election in 1945, it restricted its powers of its own accord. It put the constitution of 1886 in force again with such amendments as constitutional science and experience had made necessary. So it came about that the statutes of 1886, revered by the people, were preserved intact basically in their political structure, with the addition of some economic, social and administrative clauses which increased the technical efficiency of the constitution. Under the new constitution, the prolongation of the president's term in office was prohibited, and the principle was affirmed that he could not be re-elected; institutions necessary for the development of the country were created, the right to rebellion was put in force again, the most important of the successes achieved by the Salva-

Routine examination at a health centre in Santa Tecla, El Salvador, one of many such centres, hospitals and jungle clinics set up in Central America during World War II through the combined aid of the U.S. and Latin-American countries

dorean people in their hard struggle for their rights; finally, the constitutional principles were laid down through which a legislative was created to work justly and carefully, a legislative which had no dictatorial force, and could not suppress its revolutionary spirit.

Short Menéndez Term.—General Menéndez set up a caretaker government dominated by the opposition. Ex-President Martínez and his family left the country under those circumstances, to live voluntarily in the United States. It appeared for a time that the country had regained a profound calm. The government of General Menéndez was almost at once recognized by the United States, Great Britain and all the countries with whom El Salvador maintained diplomatic relations. A new period of disturbance and uncertainty soon began, but it seemed to resolve itself in a gentlemen's agreement between the men directing the three branches of the government and the representatives of the armed forces. And so with the country in high tension, Oct. 20, 1944, arrived.

In the late evening of that day the national legislative assembly met in a special session, as new grave disturbances had occurred; it received President Menéndez' resignation and the proclamation of Colonel Osmin Aguirre y Salinas as his successor, designated to the executive by the army. The country saw itself thrust into a difficult situation full of alternatives; there was even the possibility that a government-in-exile might be formed in neighbouring Guatemala, which in turn might give rise to armed frontier incidents involving the two countries, which had always been on friendly terms.

Castañeda President.—On March 1, 1945, Gen. Salvador

Castañeda Castro was declared elected by the national legislative and constituent assembly; he initiated his term as president with good will and the earnest desire to promote the reconciliation of the various factions, and to restore national unity. Castañeda issued a proclamation calling for peace and unity, granted amnesty to those who were imprisoned for political reasons and demobilized the army which had been collected at the western borders of the country; through these measures the country soon returned to a normal state of affairs.

Foreign Policy.—Throughout World War II, El Salvador tried to keep alive the spirit of co-operation arising out of the struggle of the democracies. The nation was represented at such international conferences as San Francisco and Chapultepec, and the national assembly ratified the agreements reached there. On May 17, 1945, President Castañeda met the president of Guatemala, Dr. Juan José Arévalo, in San Cristóbal de la Frontera. The conversations were carried on in a very cordial spirit, and resulted in the projected formation of a progressive federation of the two countries. This great movement was retarded by material circumstances arising out of the difficult world situation, though it was later given a very strong impulse in practical ways. This idea of a steadily increasing connection with Guatemala did not in any way exclude the traditional federalist plan, as El Salvador continued to feel its indissoluble ties to the destiny of Central America, and to maintain very cordial relations with all the Central American countries.

On Sept. 12, 1946, the president of the International Court of Justice, Dr. José Gustavo Guerrero, an eminent Salvadorean attorney, invited to the city of Santa Ana the presidents of the Central American countries to dis-

cuss possible union, but only the presidents of Guatemala and El Salvador attended. The conference was held in the city hall, and the prime ministers of the two countries, Dr. Eugenio Silva Pena and Dr. Hector Escobar Serano, took part in it, as well as a large number of the foreign diplomats accredited in El Salvador, among them the United States and the Mexican ambassadors, John F. Simmons and General Dagoberto Juárez Mora, and the British minister, Norman Mayers. At 12:30 P.M. the Agreement of Federation was signed, drawn up according to the short and objective model plan of Dr. Guerrero; it essentially arranged for the formation of a juridical commission to meet in San Salvador on Dec. 1 in order to put the previous investigations in force; its basic principles were peace, nonintervention in the internal affairs of the signatory states, aid to democratic governments and co-operation amongst the people and stimulation of cultural activities and just social reforms. (S. C. C.)

Salvation Army

A religious organization, the Salvation Army operated in 98 territories of the world in 1946, preaching the gospel of Christ in 102 languages. During the decade 1937–46, it had recorded outstanding progress in its various fields of activity.

In 1937, Salvation Army work was started in the Philippine Islands and in French Equatorial Africa, and a delegation from Mexico City requested the organization to assume activities there. Activities benefiting the deaf and dumb were pioneered in Sweden, Finland, Korea, Denmark and Norway. Publication of the only magazine for deaf mutes was originated in Sweden. Norwegian Salvationists, in addition to their regular visitation, escorted deaf and dumb to meetings and back to their homes.

A new approach to family welfare work grew in the United States as Salvationists considered the family as a unit. Removal of the source of weakness in a family involved evaluating the physical, mental, moral and spiritual condition of each family member to find the proper remedy.

Early in 1938, an important crusade was announced—the International Youth Movement. The campaign aimed to teach good citizenship, self control, unity of mind and physical fitness through cultural and educational interests. In the United States, boys' clubs were established where supervised craftwork, recreational, social and spiritual relationships pointed the way to character building.

In China, although war had destroyed several Salvation Army halls, officers remained on duty, ministering first aid or providing artificial limbs and crutches. Authorities provided the organization with a truck which conveyed a 20-day food supply to 25,000 people. At Shanghai as many as 27,000 refugees were cared for, and thousands of ready-made garments and material were distributed.

Commissioner George L. Carpenter was elected the fifth International General of the organization in 1939, succeeding General Evangeline Booth.

The outbreak of war in Europe in Sept. 1939 expanded Salvation Army services, and trained workers were dispatched immediately to war zones. More than 100 huts and canteens mushroomed in or near naval and military bases in Britain, France and Finland.

Modern improvements at the Salvation Army Hospital in Anand, India, catered to as many as 300 out-patients

daily, and in-patients crowded it to twice its capacity. Medicine, X-ray facilities, major and minor operations and laboratory tests for fluid analyses, tuberculosis, typhoid, syphilis, gastric diseases and blood were offered free to people of all religious and social conditions.

At International headquarters in London, the first contingent of Salvation Army officers was organized in 1940 to serve with the British Expeditionary Forces, and a War Comforts department was founded. Mobile canteens, servicemen's hostels and Red Shield clubs were open night and day in all war areas. English military authorities requested the opening of a hospital and guest house for wounded soldiers and relatives. Mobiles provided tens of thousands of troops evacuated from Dunkirk with comforts. A railroad station hostel in England provided over 10,000 free beds to troops-in-transit. These activities typified a world-wide concentration on war work added to other emergency services and ongoing work.

Although the organization's International headquarters was destroyed during an air raid on London in 1941, administrative work continued from temporary headquarters. Elsewhere, war procedures continued with such additions as appointments of Salvation Army officers as chaplains, assumption of the responsibility for the social and religious welfare of evacuees in London, acquisition of vessels to serve seamen stationed on anchored boats off the coast and operation of a club and 13 mobiles in Singapore.

In the United States, war services of the Salvation Army were channelled through (1) clubhouses for servicemen as designated through United Service organizations (*q.v.*); (2) collection and salvage of materials valuable to defense; (3) evacuation and emergency housing for civilians; and (4) operation of mobiles at defense installations.

The organization participated in U.S.O., which joined six national welfare agencies to serve the religious, spiritual, welfare and educational needs of the armed forces and of defense workers.

The establishment of a postwar relief department in 1943 at international headquarters exemplified the organization's long-range view. On 23 fighting fronts, the Salvation Army continued filling the needs of war-worn peoples. Officers were detailed to North Africa, where the first Anglo-American service club was erected by the ministry of information following plans prepared by the Salvation Army.

During the Dieppe raid in Aug. 1943, Canadian officers accompanied the armed forces; they were also among the first in Sicily. Advancing with Gen. Douglas MacArthur's men in New Guinea, Red Shield workers established 13 recreation centres. Missionary work in East Africa advanced with the completion by Salvation Army officers of their study for a working knowledge of Kiswahili, the language chiefly used there, and subsequent printing of the Bible.

In the United States in 1944, increased effort was directed toward youth work and emphasis on war activities shifted to helping returned veterans, the bereaved and wounded. The Post War Relief department conducted correspondence courses in pertinent subjects for thousands of officers around the world to supplement their resources for dealing with distress and special emergencies.

Mass feeding was speedily organized for 20,000,000 to 30,000,000 Chinese war refugees.

By the end of World War II, the Salvation Army had carried religious and social activities to approximately 225,000,000 servicemen. By late 1945, 1,000 mobiles had

848

travelled a distance equivalent to four times around the world. Salvationists visited approximately 595,000 wounded and sick servicemen in hospitals.

While the regular network of rehabilitation services continued, other war-related developments grew: a home in France for children whose parents were dislocated, a refugee boys' home and "warphanage" in China, soldiers' and sailors' rest homes in South America and the middle east, and a motor launch to reach convoys and visit outposts on island rivers in Australia.

In the postwar period, following the Army's positive reaction to war urgency needs, the organization revamped its facilities to serve men headed overseas as replacements, to help veterans return to civilian life, to assist their wives and families and to aid hospitalized servicemen.

During 1946, Salvation Army units were pressed into service to aid in securing temporary shelter for victims of the nationwide housing shortage. Youth activities were intensified particularly during the summer months, when over 27,000 mothers and children were emancipated from the blights of city summers at Salvation Army Fresh Air Camps.

During the countrywide clothing drive, Salvation Army centres shouldered their share of the job by collecting, repairing and crating garments for the needy overseas. Local corps and other units hurried a variety of relief supplies to war-torn countries. Many Salvation Army kitchens were converted to canneries where volunteers processed food for shipment overseas. Its world-wide chain of units facilitated the task and many governments requested the organization to render more aid than ever before.

By the end of 1946, the Salvation Army had 27,995 trained officers, 5,000,000 followers, and 17,996 corps and outposts.

Samoa, American

American Samoa comprises the island of Tutuila and all other islands of the Samoan group east of longitude 171° W., including Aunu'u, Tau, Olosega, Ofu and Swains islands and Rose atoll. For several years prior to 1899 the interests of the United States, Great Britain and Germany in the Samoan Islands had been the subject of misunderstanding and controversy. On Dec. 2, 1899, a tripartite convention between these three powers was signed in Washington; Germany was awarded those islands of the Samoan group west of longitude 171° W. and the United States was to receive such islands of the group as were east of that line.

The former German islands were mandated to New Zealand following World War I.

On April 17, 1900, the high chiefs of Tutuila ceded the islands of Tutuila and Aunu'u to the United States. However, it was not until July 14, 1904, that the Manua Islands of Tau, Olosega and Ofu were ceded by the high chiefs. Correspondingly, congress did not formally accept these cessions until Feb. 20, 1929. Jurisdiction was extended over Swains Island and the uninhabited Rose atoll by a joint resolution of congress on March 4, 1925. On Feb. 19, 1900, shortly following the Tripartite convention, the president, by executive order, placed the islands of American Samoa under the jurisdiction of the secretary of navy for purposes of administration.

The natives of American Samoa are Polynesian and are closely related to the natives of Hawaii and the Maoris of New Zealand. According to an official census on April 1, 1940, the population was 12,908. The Samoan language is probably the oldest form of Polynesian speech extant. It is closely related to the Maori, Tahitian, Hawaiian and Tongan languages.

Samoa differs from most large Polynesian communities in its system of chieftainships. The basis of this organization is an intricate system of graded titles. Essentially these titles are of two kinds—*Ali'i* and *Tulafale*. It is difficult to translate these terms precisely, but the former might be called titular chiefs and the latter orator chiefs. They are commonly referred to as chiefs and talking chiefs respectively.

All chiefs of Samoa are referred to by the generic term *Matai*.

Succession to a title is elective within a family and while heredity is a contributory qualification, general ability, popularity and the capacity to make a good speech are the principal considerations borne in mind when a title is to be filled.

Under such a system no feudal government based on the conception of a purely hereditary aristocracy had arisen by the end of 1946. The *Tulafale* or talking chiefs form a distinct class in Samoan society. They are ordinarily outstanding characters and natural leaders. They speak on behalf of chiefs (*Ali'i*) at important functions and place before the chiefs the wishes or the complaints of the people they represent.

All *Matai* sit in the village, county and district *fonos* (councils). In addition, they represent the respective districts at the annual *fono* or general assembly.

Kinship ties are very important in Samoan social and economic life. All who are related by birth or adoption, through both male and female lines, are recognized as belonging to one kinship or family group. Land was held formerly by the whole family group and administered or distributed by the *Matai*. However, during the decade 1937-46 the tendency was to recognize the occupier as the owner of the land.

This trend was given impetus by the war in the Pacific. Contact with large numbers of United States military personnel during the early stages of the war and the growing number of part-Samoan children, incidental to the war, tended to weaken the position of the *Matai*, especially in regard to the institution of private property. Modern education and certain governmental regulations and controls also contributed to modify the position and authority of the *Matai* in Samoan society.

There was also a remarkable trend away from "bush medicine" and a desire manifest by the native population for modern medical and surgical treatment. In 1945 alone, more than 400,000,000 units of penicillin were used in the treatment of yaws.

The results were phenomenal. Six Samoans were assigned to the 1946 class of the Native Medical Practitioners school at Guam.

The economic resources of American Samoa are of slight importance. The principal products of production are copra and mats woven from local grass and leaves. While World War II temporarily disrupted the Samoan economy, it was not believed that any profound changes would result therefrom.

Sand and Gravel

There is little that is melodramatic in the uses of sand and gravel; they were not used in the concoction of a secret weapon to annihilate the axis in World War II, or in any piece of cunning strategy to confound its evil purposes. Yet in spite of the fact that some 90% of the total output of these products during the war years went

into such prosaic uses as buildings, paving and railway ballast, and the remainder into various industrial applications, sand and gravel did their full share in contributing to the war program in the construction of munitions plants and of housing for the workers, in airfield runways and essential highways and in a score of lesser ways.

In the accompanying tabulation of the production of sand and gravel in the United States, and their distribution by uses, one can trace the effects of World War II along every line. Consumption in building and paving work expanded rapidly, reaching a peak in 1942. After the bulk of war construction work had been completed, these uses shrank heavily, and it was only with the beginning of the postwar housing program in 1945 that there was an upturn in this type of consumption. Other applications, connected with industrial processes and the transportation of industrial products developed somewhat more slowly, but in many cases to a later and relatively higher peak. Most of these applications did not begin to decline until 1944, and then only to a minor degree.

The only other country for which statistics were available was Canada, where progress was of much the same order as in the United States, though of course on a smaller scale, and with the effects of war construction less pronounced. Production of sand and gravel in Canada during the decade was as follows, in short tons:

1937	27,001,301	1942	29,349,907
1938	32,223,882	1943	25,744,469
1939	31,294,341	1945	28,399,986
1940	31,375,415	1946	29,021,249
1941	31,604,806		

From these figures it is to be noted that the postwar building program got under way in Canada a year earlier than in the United States, and also that the per capita production was greater; while Canada had only about 9% of the population of the United States, the output of sand and gravel was 13% of that of the United States.

San Francisco

After the Japanese attack on Pearl Harbor, San Francisco became the principal mainland base for the United States war in the Pacific. Facilities around the 450 sq.mi. land-locked San Francisco bay were quickly expanded. They included Mare Island navy yard at Vallejo, Hunters Point navy yard at San Francisco, numerous supply depots, cantonments and training centres, a score of shipyards and

a large and diversified industry. Nearly one-third of all ships produced in the U.S. during the war were built on the bay.

San Francisco became virtually the west coast capital of the U.S. during the war. Here were army and navy headquarters and 110 agencies of the armed services. Some 200 other federal agencies of wide regional jurisdiction were increased to 262.

The United Nations Conference on International Organization met in San Francisco from April 25 to June 26, 1945, drafted and adopted the United Nations charter.

Resident population within the 44.82 sq.mi. land area of the city and county of San Francisco increased from an estimated 634,498 in 1937 to 827,400 in 1946, while that of all the nine counties around the bay increased from 1,690,000 to 2,543,100.

Persons employed in San Francisco in 1946 were estimated at about 400,000, which compared with about 315,000 in 1937. Comparable figures for the nine-county bay area were 940,000 and 660,000. The wages in the manufacturing industries in the San Francisco-Oakland area (five counties) increased from \$122,916,300 in 1937 to about \$475,000,000 for the year ending Dec. 31, 1945.

The San Francisco Employers council was organized in 1939 to attempt to adapt to the local situation the principles of labour-and-management organization as followed in England and Sweden. Its beginning membership of 1,100 employers was increased to 2,200 by July 1, 1946. The council advocated industry group collective agreements with labour unions. In seven years it negotiated more than 1,000 such agreements and settled about 2,000 labour controversies. Strikes in the city decreased from year to year. In 1945 it had only 18, according to the bureau of labour statistics of the U.S. department of labour. This ranked San Francisco 30th among 89 U.S. cities that had ten or more strikes.

Business activity in San Francisco during 1945, as measured by cash income of civilian residents, amounted to \$1,619,566,000 as compared to \$739,000,000 in 1937, or an increase of 119%. San Francisco bank debits for 1945 were \$21,248,370,000 or about \$10,256,000,000 more than for 1937, while bank clearings for 1945 amounted to \$15,743,541,000, compared with \$7,913,846,000 in 1937. Retail sales in San Francisco for 1945 were estimated at \$846,081,000 or about \$456,000,000 more than in 1937. Sales at wholesale rose to an estimated total of \$3,016,258,000 for 1945 or \$1,729,000,000 more than the 1937 estimate.

San Francisco became united with the rest of the bay area by the building of two great bridges, largest in the world, across the bay. The San Francisco-Oakland bay bridge was opened to traffic on Nov. 12, 1936, and the Golden Gate bridge on May 27, 1937. The San Francisco-Oakland bay bridge, costing \$80,000,000, was financed through the sale of bonds, to be retired out of revenue. The bridge had been crossed by 157,363,833 motor vehicles and more than 152,080,000 train passengers by June 30, 1946. Revenues collected up to that time were \$51,765,435.08. The Golden Gate bridge, costing \$35,000,000, was also financed through the sale of revenue bonds. Up to June 30, 1946, the bridge had been crossed by 43,807,846 vehicles, and the revenues collected amounted to \$21,875,900.66. (See BRIDGES.)

To celebrate completion of the bridges, the city held the Golden Gate International exposition on man-made Treasure Island in mid-bay for 254 days in 1939 and 128

days in 1940. The total number of visitors to the exposition for the two periods was about 17,000,000. Out-of-state tourists in California during the two years of 1939 and 1940 numbered 2,530,643 and their expenditures within the state totalled \$328,762,470, according to Californians Inc. (See FAIRS, EXHIBITIONS, EXPOSITIONS.)

Mayor Roger D. Lapham took office on Jan. 8, 1944. Under his tutelage the people voted on May 16, 1944, for unification of the city's streetcar systems and payment of \$7,500,000 for the privately-owned Market street railway. On Nov. 6, 1945, they voted a bond issue of \$20,000,000 for improvement of San Francisco airport, to make it second in size only to New York's La Guardia field. Work began on May 27, 1946.

A petition for the recall of the mayor, supposedly inspired by a streetcar fare increase from seven cents to ten cents, resulted in his retention at an election on July 16, 1946.

San Francisco partially solved its automobile parking problem by building a four-story underground garage beneath Union square in the downtown shopping district. Opened to the public on Sept. 12, 1942, it had a capacity of 1,700 cars and cost \$1,550,000.

During the decade 1937-46, 1,200 conventions held in San Francisco attracted almost 1,000,000 visitors, who spent an estimated \$65,250,000 in the city. (R. D. L.)

San Marino

The tiny republic of San Marino is situated on the eastern slopes of the Etruscan Apennines in the Italian peninsula. Area: 38 sq.mi. Population (1939), 14,547. Chief town: San Marino. Legislative power was vested in the grand council of 60 elected members, two appointed every six months to act as regents.

In April 1939 San Marino renewed her treaty of friendship with Italy, but on the outbreak of World War II remained neutral. On Aug. 3, 1943, the fascist grand council was dissolved and a provisional council appointed; San Marino thus returned to her old democratic traditions. In the autumn of 1944, when the fighting in Italy seemed likely to engulf San Marino, this small state emphatically asserted its neutrality, but the Germans violated it, and on Sept. 19 and 20 Canadian troops entered the republic, after which San Marino declared war on Germany. A new treaty with Italy was signed in March 1946. (J. RA.)

Sapieha, Adam Stefan

Cardinal Sapieha (1867-), Polish prelate, was born May 14, 1867, at Krasiczyn, Poland. Preparing for the priesthood, he studied theology at Innsbruck and Rome, and was ordained in 1893. He was named president of

"The Rock", a Christian social organization in 1904, and was appointed adviser to the Vatican on Polish affairs the following year.

He was named bishop in 1911 and was elevated to archbishop in 1925, when the Cracow diocese was lifted to the status of an archdiocese.

Archbishop Sapieha, who had strong feelings with regard to questions of propriety and public morality, at one time created a sensation by his refusal to admit King Carol of Rumania, then in Poland on an official visit, into the Cracow cathedral because of the king's relationship with Mme. Lupescu. During World War II, he locked the doors of the Wawel cathedral in 1940 to prevent nazi ingress and personally retained the keys. Nominated to the Sacred College of Cardinals Dec. 23, 1945, he was created and proclaimed a cardinal at the consistory of Feb. 18, 1946.

Sapru, Sir Tej Bahadur

Sir Tej Sapru (1875-), Indian judge and government official, was born Dec. 3, 1875. He was educated at Agra college and practised law at Allahabad, where he achieved a reputation as one of India's most brilliant lawyers. He later became president of the Indian Liberal federation.

Sapru played a prominent part in the Round Table conferences in London in 1930-32. He also served on the United Provinces Legislative council and on the Imperial Legislative council. As a representative of the non-party group, he had several discussions with Sir Stafford Cripps during the latter's first mission to India and in July 1942 suggested that Britain unequivocally grant India complete self-government within a year after the end of World War II.

Saracoglu, Shukru

Saracoglu (1890?-), Turkish statesman, was born in Odemis, Turkey. Educated in Turkish civil service schools, he studied law at Lausanne university, Switzerland. He served in the Turkish army during World War I, joined Mustafa Kemal Pasha (Kemal Ataturk) after the armistice and fought against the Greek forces in 1921. After the abolition of the sultanate, Saracoglu became a member of the national assembly as deputy from Izmir, rising high in the councils of Mustafa Kemal's party. During his tenure as minister of justice (1932-38), he brought about numerous legal reforms and continued Kemal's work of westernizing Turkish institutions and customs.

Named foreign minister after Kemal's death in 1938, Saracoglu followed a consistent policy of neutrality during the first years of World War II. In July 1942 he was named prime minister, and after the re-election of President Ismet Inönü in March 1943, Saracoglu headed a re-organized cabinet. On June 15, 1944, he assumed the portfolio of foreign affairs when the incumbent, Numan Menemencioglu, resigned in a dispute over whether German ships should be allowed to pass through the Dardanelles. Saracoglu promised at that time, although Turkey was still neutral, that Turkish "might and right" would not be used against the Allies, and on Aug. 2, 1944, he an-

nounced that Turkey had broken relations with Germany at the request of Great Britain and the United States. Saracoglu resigned as premier, Aug. 4, 1946, and was succeeded by Recep Peker.

Sarawak

See BORNEO, BRITISH; BRITISH EMPIRE.

Saskatchewan

Created by an act of parliament on Sept. 1, 1905, as the central Canadian "prairie province," Saskatchewan is more prairie-like than Manitoba on the east or Alberta on the west. But its top third, meeting the Northwest Territories, is true "North Country" of many lakes and rivers and dense bush. Of its 251,700 sq.mi., 13,725 are water. The bottom third of the province, similar to Montana and North Dakota on which it borders, is an extension of the U.S. great central plain.

In 1941, Regina, the capital, had a population of 58,245 and the other centres were Saskatoon (43,027), Moose Jaw (20,753), Prince Albert (12,508). The decade 1937-46 saw unusual shifts in the province's make-up. Affected first by drought conditions and later by the impact of World War II, people began moving from the country to the towns and cities. The population, however, remained preponderately rural. Of the 921,281 in the 1931 census, only 290,905 were urbanites; and of the 895,992 in 1941, only 295,146. These figures indicate another effect of drought and the war: Saskatchewan lost many of its people to other Canadian provinces, and in 1946 the decline was still in evidence, with the dominion bureau of statistics estimating a further drop in population to 845,000. Although some of the loss was recovered by the return of war veterans, the federal Redistribution act of 1946 indicated the long-range aspects of the decline; Saskatchewan's representation in the house of commons (based on population) dropped from 21 to 20. In 1941 the four main racial groups in order of size were British, German, Ukrainian and French; and the four largest religious bodies in order of strength were Roman Catholic, United Church of Canada, Anglican and Lutheran.

Lieutenant-governors for the 1937-46 decade were: A. P. McNab (Oct. 1, 1936-Feb. 27, 1945); Thomas Miller (Feb. 27, 1945-June 22, 1945); R. J. M. Parker (after June 22, 1945). Premiers were: W. J. Patterson (Nov. 1, 1935-July 10, 1944), T. C. Douglas (after July 10, 1944).

Despite the hardships suffered during the drought in the latter part of the 1930s, and despite the population losses caused by World War II, Saskatchewan prospered during the decade 1937-46. Largely dependent on agriculture, which in 1945 provided 58% of her employment and 86% of her total production, the province experienced steady expansion in value of farm products, farm cash income, and farm investment capital. The latter was an expression of confidence in Saskatchewan's agricultural future, which was underlined by the creation in 1944 of a \$200,000 agricultural research laboratory empowered not only to help maintain farm productivity but also to find new uses for the province's main crops.

Industrially, too, Saskatchewan showed marked expansion during the decade. The number of factories increased by almost half, the number of employees and the amount of capital invested almost doubled, while the value of goods produced more than doubled. There was proportionate activity in raw materials production, especially in mining; the big zinc-copper mine at Flin Flon hit its stride, and helped to increase annual mineral production from \$6,970,000 to \$22,291,000.

As a result of this agricultural and industrial expansion during the decade, Saskatchewan's financial position improved. In 1939 the province's share of the national income was \$236 per person: by 1944 the figure had increased to \$483.

The most interesting developments during the decade were political in nature. For the second time in the history of the province the Liberals suffered defeat at the polls. From 1905 to 1944 there had been a line of Liberal regimes broken only by the Conservative government of 1929-34; but in 1944 the left-wing Co-operative Commonwealth Federation swept all but five Liberals out of the 55-seat legislature.

At its first session in 1944, the Douglas government passed a legislative record of 120 laws, many of them socialistic. New departments were set up. The department of reconstruction and rehabilitation, first in Canada, was given jurisdiction over housing, rural electrification, rural plumbing and co-operative farming. The department of co-operation and co-operative development was given power to legislate for commercial co-operatives: with 513 co-operatives in 1943, this department reported a peak of 876 co-operatives at the end of 1945, with a membership of 229,000, and annual business worth \$199,000,000. The department of natural resources and industrial development had power over the utilization of natural products; by 1946, the Douglas government was operating lumbering, fish-filleting, woollen, leather, shoe, sodium-sulphate, brick, fur-marketing, electric-power, and highway bus-line enterprises.

The department of labour, which the C.C.F. administration also established, in view of the increasing industrialization of Saskatchewan, consolidated and revised various provincial labour laws already on the statute books, and enacted many new ones, such as comprehensive legis-

lation respecting minimum wages, apprenticeship and labour relations.

A marketing board was set up with wide powers over the handling of natural products. With an eye to increasing income available from the fish resources of the North Country lakes, which had expanded from \$250,000 to \$1,482,000 in the decade, the government in 1945 empowered a royal commission to study fish production, processing and marketing.

The following year an important fur conservation scheme got under way, with the white and Indian trappers of the North Country co-operating readily.

Besides putting into effect unusual economic and social policies, the C.C.F. government was active in other spheres. It began operating the first provincially-owned air ambulance capable of flying emergency cases from isolated areas to hospitals. It instructed the provincial university to open courses in Russian, the first Canadian university to do so. It imported a special instructor in basic English to teach a group of special teachers, and then sent the teachers among the 63,881 Saskatchewanites who in 1946 still could not speak either English or French.

As might be expected, the challenges by left-wingers of the tenets of liberalism were not unopposed by the Liberals. At a provincial convention in 1946 the former Liberal premier and provincial leader, W. J. Patterson, was deposed, and Walter A. Tucker, Liberal member of parliament for Rosthern, was put in control of Saskatchewan Liberal policies. He at once set about closing the ranks of liberalism.

854 Sauckel, Fritz

Sauckel (1894–1946), German politician, was born Oct. 27, 1894, in Lower Franconia. A seaman during World War I, his ship was captured by the British in the English channel and he spent the remainder of the war as a prisoner in England. Sauckel joined the Nazi party at its inception and became one of its leading propagandists in Lower Franconia. He became a Nazi group leader in Thuringia and later a member of the provincial diet. He subsequently served as minister of the interior and state commissioner.

During World War II, Sauckel was chief commissioner for the utilization of manpower and met Hitler's request for greater production by rounding up slave labourers for Germany's factories. Travelling through Nazi-occupied territories in Europe, he recruited slave labour by force. After the war, he was brought to trial at Nuremberg before the international military tribunal along with other Nazi leaders and was found guilty, on Oct. 1, 1946, of war crimes and crimes against humanity and was sentenced to hang. In the verdict Sauckel was described as being in charge of a program involving deportation for slave labour of 5,000,000 people under cruel and insufferable conditions. He was hanged on Oct. 16, 1946.

Savage, Michael Joseph

Savage (1872–1940), New Zealand statesman, was born in Benalla, Australia, March 7, 1872. He left school at the age of 14 and worked successively as a clerk in a store, as a labourer on a sheep ranch and as a miner. In 1900 he became secretary of the Political Labour Council in Victoria and organized a co-operative store. He went to New Zealand in 1907 and became an active leader in the labour movement there. Elected to the house of representatives in 1919, he succeeded to leadership of the Labour party in 1933. In 1935 he became prime minister in the first labour government. The party increased its majority in the elections three years later and Savage continued in power. He died in Wellington, N.Z., March 26, 1940.

Sayre, Francis Bowes

Sayre (1885–), U.S. statesman and lawyer, was born April 30, 1885, at South Bethlehem, Pa. He received his A.B. degree from Williams College in 1909 and his LL.B. degree from Harvard University in 1912. In 1913 he married Jessie Woodrow, daughter of President Wilson, at the White House. (She died Jan. 15, 1933). He was a teaching fellow at Harvard Law School (1917–18), and from 1919 to 1934 he remained on Harvard's faculty, becoming director of the university's Institute of Criminal Law.

Sayre was appointed assistant secretary of state by President Roosevelt in 1933 and U.S. high commissioner to the Philippines in 1939. In Manila during the Japanese attack, Sayre lived for two months in the Corregidor fortress. Taken off by a U.S. submarine, he returned to Washington, D.C., in the spring of 1942. In 1944 he was appointed diplomatic adviser to the director general of U.N.R.R.A. Testifying in the postwar Pearl Harbor

inquiry, Sayre introduced in evidence, Dec. 4, 1945, a message from Pres. Roosevelt, dated Nov. 26, 1941, which warned that Japan was planning an attack against Allied outposts in the Pacific and far east.

Scandinavian Literature

The Scandinavian nations maintained and strengthened their literary tradition through the decade 1937–46. Poetry and action are close cousins in the north; invasion and terror redirected the thought and gave new fire to the writing of the 20th century *skalds*.

Norway.—The Norwegian government made Nordahl Grieg a new kind of poet laureate, official inspirer of troops and people. His mind was keen and mature, and he lived and acted with soldiers and sailors; he lost his life in a bombing raid over Berlin in Dec. 1943. Another of the voices of Norway during the early days of World War II was Arnulf Overland, later imprisoned three years by the Germans. His "We Shall Live Through All" was perhaps the greatest poem of the period out of Norway. A third who could put in words that inner strength that kept his country strong was Sigmund Skard. And last but not least in a notable group was Gunnar Reiss-Andersen, who wrote movingly and effectively from exile in Sweden.

Novels and criticism awaited peaceful times, though the night lectures of Francis Bull in the concentration camp at Grini brought heart to his fellow prisoners through his interpretations of Bjørnstjerne Bjørnson and Henrik Ibsen and Henrik Wergeland. Literature was a potent living force, which explains why Nazi sympathizers such as the aged Knut Hamsun were doubly anathema to their people. Others of the older group, such as Sigrid Undset and Fredrick Paasche, spoke out vigorously abroad for their nation, and Halvdan Koht continued his prolific historical writing in the United States. In the early years of World War II some notable works were published: e.g., Johan Bojer's reminiscences, *Prentice Boy*, Johan Falkberget's imaginative *The Bread of Night* and Inge Krokmann's historical *Under the Sign in the Sky*.

Denmark.—In Denmark literature played a role similar to that in Norway, through quite different personalities. The giant of the times was Kaj Munk, pastor and playwright, murdered by the Nazis in 1944; his martyrdom hardened the steel of Danish resistance. In 1942 Munk published *The Spring Comes Gently*, a richly thoughtful study of his own spiritual growth and of the problems of youth. In the same year came out the quickly prohibited *Niels Ebbesen*, pointed drama of the 14th century assassination of a German bully. Fame was won through plays and poetry; influence waxed with sermons which rang a challenge throughout the nation and goaded the invaders into violent action (some published as *The Sword of the Word*).

Karen Blixen (Isak Dinesen) was known for her *Seven Gothic Tales*, and in 1942 published the similar-in-spirit *Winter's Tales*. Martin Andersen Nexø (*Pelle the Conqueror*), had to flee Denmark to U.S.S.R. because of his too great sympathy for the Soviets, but returned and was feted on his 76th birthday. Johannes V. Jensen (*The Long Journey*, etc.), turned in his later years to studies in evolution; in 1943 he celebrated his 70th birthday, and soon thereafter was awarded the Nobel prize—the act itself a Swedish gesture of defiance against the Nazis. Henrik Pontoppidan, last survivor of "the authors of the Modern Awakening," a Nobel winner of 1917, was silent in these latter years. Of the newer group of writers, one of the most brilliant was Mogens Klitgaard, whose *Tragi-Comedy at Nytorv* was an 18th century period piece on sex. Mystical and metaphysical tendencies were represented by

Aage Dons (*Where All Roads Meet*), H. C. Branner (*A Dream about a Woman*) and Tove Ditlevsen (*A Child was Harmed*).

Sweden.—Sweden, untouched physically by invasion, was touched deeply in soul by the surrounding conflict. National sentiment and ideals of Nordic brotherhood appeared in such form as the lyric poetry of Gunnar Mascoll Silfverstolpe (*My Country*), and Pär Lagerkvist (*Song and Battle*). More personal in reaction to the stifling brutality of the day was Karin Boye.

Of the later Swedish writers on the psychological problems of bourgeois life, perhaps the ablest was Olle Hedberg (*Josephine: or Say It with Flowers*, and *What Is the Toy-Chest Sighing?*). A revaluation and re-emphasis on the democratic way of life was seen in Eyvind Johnson's *The Krilon Group*, a powerful political novel. Dramatic in intensity and widely popular was Wilhelm Moberg's *Ride This Night!*, a historical novel of a 17th century peasant uprising. Frans G. Bengtsson's *The Red Serpent* also became a best-seller.

Pär Lagerkvist stood above all contemporary dramatic writers, his *Victory in the Dark* being especially notable. Karl Ragnar Gierow (*The Werewolf*) and Sven Stolpe (*Döbeln*) both gave promise for the future.

During the decade Sweden suffered loss in the death of many of her greats: the beloved Selma Lagerlöf, the historical novelist Verner von Heidenstam, witty Albert Engström, art historian Carl G. Laurin, poets Erik Lindorm, Gunnar Silfverstolpe and Karin Boye and others less well-known abroad.

Iceland.—Iceland, like the other Scandinavian lands, published a great number of translations of American and British authors. Works from sisterlands to the east were adapted, too: Nordahl Grieg's last volume, *Freedom*, was first published in Iceland, and Kaj Munk's *Niels Ebbesen* was first performed there. Iceland's own artists were also productive. Out of the wealth of novels, Halldór Laxness' *Independent People*, historical and interpretive, was noteworthy. In 1942 appeared volume one of Iceland's first real cultural history, *Islenzk Menning*, by Sigurdur Nordal.

Schacht, Hjalmar Horace Greeley

Schacht (1877-), German financier, economist and politician, was born Jan. 22, 1877, at Tinglev near Flensburg. A student of political economy, he was associated with a number of German banks in high executive positions and was appointed president of the reichsbank in 1923. Because of his opposition to the Young plan, he resigned from the reichsbank in 1930. Generally regarded as a financial "wizard," Schacht was reinstated as president of the reichsbank by Adolf Hitler in 1933. He had actively supported the nazi party before its accession to power and endorsed Hitler's appointment as chancellor.

Schacht instituted the system of exchange control, which bolstered Germany's weak foreign exchange position and facilitated the purchase abroad of raw materials required for the war effort. In 1936 his position as the top authority on German war economics was undermined by Hermann Goering, who became co-ordinator for raw materials and foreign exchange. Schacht opposed Goering's program of economic self-sufficiency. However, Hitler sided with Goer-

ing and on Nov. 16, 1937, Schacht resigned his post as minister of economics and plenipotentiary general for war economy, to which he had been named in 1934.

Thereafter, Schacht emerged in a new role—that of an opponent of "excessive militarization." He presented (Jan. 2, 1939), a report to Hitler urging a sweeping reduction of arms expenditures and establishment of a balanced budget as the only means of preventing inflation. Hitler disagreed and on Jan. 19, 1939, ousted Schacht as president of the reichsbank. Schacht retained his post as minister without portfolio until Jan. 22, 1943, when Hitler forced him out of that position too.

Schacht participated in the abortive plot to assassinate Hitler July 20, 1944. Three days later, he was arrested and confined in a concentration camp until the end of World War II. He was subsequently released by the Allied authorities and on Aug. 29, 1945, was indicted by the International War Crimes tribunal at Nuernberg to stand trial on charges of various war crimes. He was acquitted on Oct. 1, 1946, by the tribunal, which ruled that while he undoubtedly was the central figure in the German rearmament program, rearmament itself was not criminal under the court's charter. The court further stated that there was no evidence to indicate that Schacht carried out this rearmament as part of a nazi plan to wage aggressive war. After his release, Schacht was again arrested, Oct. 7, 1946, by German police at Backnang to stand trial before a German denazification court.

Schuschnigg, Kurt von

Schuschnigg (1897-), Austrian statesman, was born Dec. 14, 1897, at Riva (then in Austria, later in Venetia Tridentina, Italy). He served in the Austro-Hungarian forces in World War I, was taken prisoner by the Italians in 1917 and was released after the war. Entering politics in 1927, he held successively the ministries of justice and education in Chancellor Engelbert Dollfuss' government. After becoming chancellor in 1934, he forced the ouster of his vice-chancellor, Prince Ernst von Starhemberg; he also dismissed the interior minister, Herr von Sturmer, assuming that portfolio himself.

As Adolf Hitler exerted pressure for an anschluss, Schuschnigg proclaimed a plebiscite for March 13, 1938, in an effort to rally Austrian opinion for continued independence. Moving quickly to forestall a vote, Hitler marched into Austria on March 12, 1938, and annexed the country. Schuschnigg was promptly jailed as a "traitor" to the "Germanic folk" of Austria. While in prison Schuschnigg, through the intercession of the Catholic Church, was permitted to marry by proxy Countess Vera Fugger-Czernin on June 1, 1938. Later, the Schuschniggs were permitted to reside in a Bavarian village, although still under German custody.

During the final phases of the war, the Schuschniggs were transferred to the Pragser Wildersee concentration camp in the Italian Alps, from which they were liberated in May 1945 by U.S. 5th army troops. They then moved to the Isle of Capri, off Italy. They went to the U.S. in 1947 and Schuschnigg was appointed to the faculty of Fordham university.

856 Schwellenbach, Lewis Baxter

Schwellenbach (1894–), U.S. jurist and cabinet member, was born Sept. 20, 1894, in Superior, Wis. A graduate of the University of Washington, Seattle, he received his LL.B. degree in 1917 and served with the U.S. army as a private during World War I. After the war he returned to Washington, where he was admitted to the bar in 1919. Becoming active in state politics, he was elected in 1934 to the U.S. senate on the Democratic ticket. During his tenure, he supported the administration in both its domestic and foreign policies. He resigned from the senate in Dec. 1940 to become federal judge of Washington state, eastern district.

On May 23, 1945, President Truman named him secretary of labour. The appointment won approval from both the A.F. of L. and the C.I.O., and he assumed office on June 30. In 1945 Secretary Schwellenbach advocated raising the minimum wage law to 65 cents an hour and urged legislation to this end. He also favoured equal pay for women and legislation banning pay differentials based on sex. Throughout 1945 and 1946 the secretary of labour was beset with many vexing problems, including the oil and automobile industry strikes in 1945, the steel strike in 1946 and the two coal walk-outs engineered by John L. Lewis in 1946. He evolved the fact-finding procedure for settlement of strikes and tried his hand at labour mediation, succeeding in some cases, failing in others.

Science, Future Techniques of*

Of what lasting benefit has been man's use of science and of the new instruments which his research brought into existence? First, they have increased his control of his material environment. They have improved his food, his clothing, his shelter; they have increased his security and released him partly from the bondage of bare existence. They have given him increased knowledge of his own biological processes so that he has had a progressive freedom from disease and an increased span of life. They are illuminating the interactions of his physiological and psychological functions, giving the promise of an improved mental health.

Science has provided the swiftest communication between individuals; it has provided a record of ideas and has enabled man to manipulate and to make extracts from that record so that knowledge evolves and endures throughout the life of a race rather than that of an individual.

There is a growing mountain of research. But there is increased evidence that we are being bogged down today as specialization extends. The investigator is staggered by the findings and conclusions of thousands of other workers—conclusions which he cannot find time to grasp, much less to remember, as they appear. Yet specialization becomes increasingly necessary for progress, and the effort to bridge between disciplines is correspondingly superficial.

Professionally our methods of transmitting and reviewing the results of research are generations old and by now are totally inadequate for their purpose. If the aggregate time spent in writing scholarly works and in

reading them could be evaluated, the ratio between these amounts of time might well be startling. Those who conscientiously attempt to keep abreast of current thought, even in restricted fields, by close and continuous reading might well shy away from an examination calculated to show how much of the previous month's efforts could be produced on call. Mendel's concept of the laws of genetics was lost to the world for a generation because his publication did not reach the few who were capable of grasping and extending it; and this sort of catastrophe is undoubtedly being repeated all about us, as truly significant attainments become lost in the mass of the inconsequential.

Science's Need for New Methods of Recording.—The difficulty seems to be, not so much that we publish unduly in view of the extent and variety of present-day interests, but rather that publication has been extended far beyond our present ability to make real use of the record. The summation of human experience is being expanded at a prodigious rate, and the means we use for threading through the consequent maze to the momentarily important item is the same as was used in the days of square-rigged ships.

But there are signs of a change as new and powerful instrumentalities come into use. Photocells capable of seeing things in a physical sense, advanced photography which can record what is seen or even what is not, thermionic tubes capable of controlling potent forces under the guidance of less power than a mosquito uses to vibrate his wings, cathode ray tubes rendering visible an occurrence so brief that by comparison a microsecond is a long time, relay combinations which will carry out involved sequences of movements more reliably than any human operator and thousands of times as fast—there are plenty of mechanical aids with which to effect a transformation in scientific records.

Two centuries ago Leibnitz invented a calculating machine which embodied most of the essential features of recent keyboard devices, but it could not then come into use. The economics of the situation were against it: the labor involved in constructing it, before the days of mass production, exceeded the labor to be saved by its use, since all it could accomplish could be duplicated by sufficient use of pencil and paper. Moreover, it would have been subject to frequent breakdown, so that it could not have been depended upon; for at that time and long after, complexity and unreliability were synonymous.

Charles Babbage, even with remarkably generous support for his time, could not produce his great arithmetical machine. His idea was sound enough, but construction and maintenance costs were then too heavy. Had a Pharaoh been given detailed and explicit designs of an automobile, and had he understood them completely, it would have taxed the resources of his kingdom to have fashioned the thousands of parts for a single car, and that car would have broken down on the first trip to Giza.

Machines with interchangeable parts can now be constructed with great economy of effort. In spite of much complexity, they perform reliably. Witness the humble typewriter, or the movie camera, or the automobile. Electrical contacts have ceased to stick when thoroughly understood. Note the automatic telephone exchange, which has hundreds of thousands of such contacts, and yet is reliable. A spider web of metal, sealed in a thin glass container, a wire heated to brilliant glow, in short, the thermionic tube of radio sets, is made by the hundred million, tossed about in packages, plugged into sockets—and it works! Its gossamer parts, the precise location and alignment

* Reprinted by permission of the copyright owners from the *Atlantic Monthly* for July 1945, where it appeared under the title "As We May Think." Because of the importance of this speculative essay by Dr. Vannevar Bush, which emphasizes the need for making man's vast accumulation of knowledge more accessible to all, and points out potentially practicable ways of meeting that need—the editors of *Britannica* have reproduced the fantasy in full, except for short introductory paragraphs.

involved in its construction, would have occupied a master craftsman of the guild for months; now it is built for thirty cents. The world has arrived at an age of cheap complex devices of great reliability; and something is bound to come of it.

New Uses of Photography.—A record, if it is to be useful to science, must be continuously extended, it must be stored, and above all it must be consulted. Today we make the record conventionally by writing and photography, followed by printing; but we also record on film, on wax disks, and on magnetic wires. Even if utterly new recording procedures do not appear, these present ones are certainly in the process of modification and extension.

Certainly progress in photography is not going to stop. Faster material and lenses, more automatic cameras, finer-grained sensitive compounds to allow an extension of the minicamera idea, are all imminent. Let us project this trend ahead to a logical, if not inevitable, outcome. The camera hound of the future wears on his forehead a lump a little larger than a walnut. It takes pictures 3 millimeters square, later to be projected or enlarged, which after all involves only a factor of 10 beyond present practice. The lens is of universal focus, down to any distance accommodated by the unaided eye, simply because it is of short focal length. There is a built-in photocell on the walnut such as we now have on at least one camera, which automatically adjusts exposure for a wide range of illumination. There is film in the walnut for a hundred exposures, and the spring for operating its shutter and shifting its film is wound once for all when the film clip is inserted. It produces its results in full color. It may well be stereoscopic, and record with two spaced glass eyes, for striking improvements in stereoscopic technique are just around the corner.

The cord which trips its shutter may reach down a man's sleeve within easy reach of his fingers. A quick squeeze, and the picture is taken. On a pair of ordinary glasses is a square of fine lines near the top of one lens, where it is out of the way of ordinary vision. When an object appears in that square, it is lined up for its picture. As the scientist of the future moves about the laboratory or the field, every time he looks at something worthy of the record, he trips the shutter and in it goes, without even an audible click. Is this all fantastic? The only fantastic thing about it is the idea of making as many pictures as would result from its use.

Will there be dry photography? It is already here in two forms. When Mathew Brady made his Civil War pictures, the plate had to be wet at the time of exposure. Now it has to be wet during development instead. In the future perhaps it need not be wetted at all. There have long been films impregnated with diazo dyes which form a picture without development, so that it is already there as soon as the camera has been operated. An exposure to ammonia gas destroys the unexposed dye, and the picture can then be taken out into the light and examined. The process is now slow, but someone may speed it up, and it has no grain difficulties such as now keep photographic researchers busy. Often it would be advantageous to be able to snap the camera and to look at the picture immediately.

Another process now in use is also slow, and more or less clumsy. For fifty years impregnated papers have been used which turn dark at every point where an electrical contact touches them, by reason of the chemical change thus produced in an iodine compound included in the paper. They have been used to make records, for a pointer moving across them can leave a trail behind. If

the electrical potential on the pointer is varied as it moves, the line becomes light or dark in accordance with the potential.

This scheme is now used in facsimile transmission. The pointer draws a set of closely spaced lines across the paper one after another. As it moves, its potential is varied in accordance with a varying current received over wires from a distant station, where these variations are produced by a photocell which is similarly scanning a picture. At every instant the darkness of the line being drawn is made equal to the darkness of the point on the picture being observed by the photocell. Thus, when the whole picture has been covered, a replica appears at the receiving end.

A scene itself can be just as well looked over line by line by the photocell in this way as can a photograph of the scene. This whole apparatus constitutes a camera, with the added feature, which can be dispensed with if desired, of making its picture at a distance. It is slow, and the picture is poor in detail. Still, it does give another process of dry photography, in which the picture is finished as soon as it is taken.

It would be a brave man who would predict that such a process will always remain clumsy, slow, and faulty in detail. Television equipment today transmits sixteen reasonably good pictures a second, and it involves only two essential differences from the process described above. For one, the record is made by a moving beam of electrons rather than a moving pointer, for the reason that an electron beam can sweep across the picture very rapidly indeed. The other difference involves merely the use of a screen which glows momentarily when the electrons hit, rather than a chemically treated paper or film which is permanently altered. This speed is necessary in television, for motion pictures rather than stills are the object.

Use chemically treated film in place of the glowing screen, allow the apparatus to transmit one picture only rather than a succession, and a rapid camera for dry photography results. The treated film needs to be far faster in action than present examples, but it probably could be. More serious is the objection that this scheme would involve putting the film inside a vacuum chamber, for electron beams behave normally only in such a rarefied environment. This difficulty could be avoided by allowing the electron beam to play on one side of a partition, and by pressing the film against the other side, if this partition were such as to allow the electrons to go through perpendicular to its surface, and to prevent them from spreading out sideways. Such partitions, in crude form, could certainly be constructed, and they will hardly hold up the general development.

Like dry photography, microphotography still has a long way to go. The basic scheme of reducing the size of the record, and examining it by projection rather than directly, has possibilities too great to be ignored. The combination of optical projection and photographic reduction is already producing some results in microfilm for scholarly purposes, and the potentialities are highly suggestive. Today, with microfilm, reductions by a linear factor of 20 can be employed and still produce full clarity when the material is re-enlarged for examination. The limits are set by the graininess of the film, the excellence of the optical system, and the efficiency of the light sources employed. All of these are rapidly improving.

Assume a linear ratio of 100 for future use. Consider film of the same thickness as paper, although thinner film will certainly be usable. Even under these conditions

there would be a total factor of 10,000 between the bulk of the ordinary record on books, and its microfilm replica. The *Encyclopædia Britannica* could be reduced to the volume of a matchbox. A library of a million volumes could be compressed into one end of a desk. If the human race has produced since the invention of movable type a total record, in the form of magazines, newspapers, books, tracts, advertising blurbs, correspondence, having a volume corresponding to a billion books, the whole affair, assembled and compressed, could be lugged off in a moving van. Mere compression, of course, is not enough; one needs not only to make and store a record but also be able to consult it, and this aspect of the matter comes later. Even the modern great library is not generally consulted; it is nibbled at by a few.

Compression is important, however, when it comes to costs. The material for the microfilm *Britannica* would cost a nickel, and it could be mailed anywhere for a cent. What would it cost to print a million copies? To print a sheet of newspaper, in a large edition, costs a small fraction of a cent. The entire material of the *Britannica* in reduced microfilm form would go on a sheet eight and one-half by eleven inches. Once it is available, with the photographic reproduction methods of the future, duplicates in large quantities could probably be turned out for a cent apiece beyond the cost of materials. The preparation of the original copy? That introduces the next aspect of the subject.

Mechanical Reproduction of Spoken Thought.—To make the record, we now push a pencil or tap a typewriter. Then comes the process of digestion and correction, followed by an intricate process of typesetting, printing, and distribution. To consider the first stage of the procedure, will the author of the future cease writing by hand or typewriter and talk directly to the record? He does so indirectly, by talking to a stenographer or a wax cylinder; but the elements are all present if he wishes to have his talk directly produce a typed record. All he needs to do is to take advantage of existing mechanisms and to alter his language.

At a recent World Fair a machine called a Voder was shown. A girl stroked its keys and it emitted recognizable speech. No human vocal chords entered into the procedure at any point; the keys simply combined some electrically produced vibrations and passed these on to a loud-speaker. In the Bell Laboratories there is the converse of this machine, called a Vocoder. The loud-speaker is replaced by a microphone, which picks up sound. Speak to it, and the corresponding keys move. This may be one element of the postulated system.

The other element is found in the stenotype, that somewhat disconcerting device encountered usually at public meetings. A girl strokes its keys languidly and looks about the room and sometimes at the speaker with a disquieting gaze. From it emerges a typed strip which records in a phonetically simplified language a record of what the speaker is supposed to have said. Later this strip is re-typed into ordinary language, for in its nascent form it is intelligible only to the initiated. Combine these two elements, let the Vocoder run the stenotype, and the result is a machine which types when talked to.

Our present languages are not especially adapted to this sort of mechanization, it is true. It is strange that the inventors of universal languages have not seized upon the idea of producing one which better fitted the technique for transmitting and recording speech. Mechaniza-

tion may yet force the issue, especially in the scientific field; whereupon scientific jargon would become still less intelligible to the layman.

One can now picture a future investigator in his laboratory. His hands are free, and he is not anchored. As he moves about and observes, he photographs and comments. Time is automatically recorded to tie the two records together. If he goes into the field, he may be connected by radio to his recorder. As he ponders over his notes in the evening, he again talks his comments into the record. His typed record, as well as his photographs, may both be in miniature, so that he projects them for examination.

Mechanizing Simple, Routine Thought.—Much needs to occur, however, between the collection of data and observations, the extraction of parallel material from the existing record, and the final insertion of new material into the general body of the common record. For mature thought there is no mechanical substitute. But creative thought and essentially repetitive thought are very different things. For the latter there are, and may be, powerful mechanical aids.

Adding a column of figures is a repetitive thought process, and it was long ago properly relegated to the machine. True, the machine is sometimes controlled by a keyboard, and thought of a sort enters in reading the figures and poking the corresponding keys, but even this is avoidable. Machines have been made which will read typed figures by photocells and then depress the corresponding keys; these are combinations of photocells for scanning the type, electric circuits for sorting the consequent variations, and relay circuits for interpreting the result into the action of solenoids to pull the keys down.

All this complication is needed because of the clumsy way in which we have learned to write figures. If we recorded them positionally, simply by the configuration of a set of dots on a card, the automatic reading mechanism would become comparatively simple. In fact, if the dots are holes, we have the punched-card machine long ago produced by Herman Hollerith for the purposes of the census, and now used throughout business. Some types of complex businesses could hardly operate without these machines.

Adding is only one operation. To perform arithmetical computation involves also subtraction, multiplication, and division, and in addition some method for temporary storage of results, removal from storage for further manipulation, and recording of final results by printing. Machines for these purposes are now of two types: keyboard machines for accounting and the like, manually controlled for the insertion of data, and usually automatically controlled as far as the sequence of operations is concerned; and punched-card machines in which separate operations are usually delegated to a series of machines, and the cards then transferred bodily from one to another. Both forms are very useful; but as far as complex computations are concerned, both are still in embryo.

Rapid electrical counting appeared soon after the physicists found it desirable to count cosmic rays. For their own purposes the physicists promptly constructed thermionic-tube equipment capable of counting electrical impulses at the rate of 100,000 a second. The advanced arithmetical machines of the future will be electrical in nature, and they will perform at 100 times present speeds, or more.

Moreover, they will be far more versatile than present commercial machines, so that they may readily be adapted

for a wide variety of operations. They will be controlled by a control card or film, they will select their own data and manipulate it in accordance with the instructions thus inserted, they will perform complex arithmetical computations at exceedingly high speeds, and they will record results in such form as to be readily available for distribution or for later further manipulation. Such machines will have enormous appetites. One of them will take instructions and data from a whole roomful of girls armed with simple keyboard punches, and will deliver sheets of computed results every few minutes. There will always be plenty of things to compute in the detailed affairs of millions of people doing complicated things.

The repetitive processes of thought are not confined, however, to matters of arithmetic and statistics. In fact, every time one combines and records facts in accordance with established logical processes, the creative aspect of thinking is concerned only with the selection of the data and the process to be employed, and the manipulation thereafter is repetitive in nature and hence a fit matter to be relegated to the machines. Not so much has been done along these lines, beyond the bounds of arithmetic, as might be done, primarily because of the economics of the situation. The needs of business, and the extensive market obviously waiting, assured the advent of mass-produced arithmetical machines just as soon as production methods were sufficiently advanced.

With machines for advanced analysis no such situation existed; for there was and is no extensive market; the users of advanced methods of manipulating data are a very small part of the population. There are, however, machines for solving differential equations—and functional and integral equations, for that matter. There are many special machines, such as the harmonic synthesizer which predicts the tides. There will be many more, appearing certainly first in the hands of the scientist and in small numbers.

If scientific reasoning were limited to the logical processes of arithmetic, we should not get far in our understanding of the physical world. One might as well attempt to grasp the game of poker entirely by the use of the mathematics of probability. The abacus, with its beads strung on parallel wires, led the Arabs to positional numeration and the concept of zero many centuries before the rest of the world; and it was a useful tool—so useful that it still exists.

It is a far cry from the abacus to the modern keyboard accounting machine. It will be an equal step to the arithmetical machine of the future. But even this new machine will not take the scientist where he needs to go. Relief must be secured from laborious detailed manipulation of higher mathematics as well, if the users of it are to free their brains for something more than repetitive detailed transformations in accordance with established rules. A mathematician is not a man who can readily manipulate figures; often he can not. He is not even a man who can readily perform the transformations of equations by the use of calculus. He is primarily an individual who is skilled in the use of symbolic logic on a high plane, and especially he is a man of intuitive judgment in the choice of the manipulative processes he employs.

All else he should be able to turn over to his mechanism, just as confidently as he turns over the propelling of his car to the intricate mechanism under the hood. Only then will mathematics be practically effective in bringing the growing knowledge of atomistics to the useful solution of the advanced problems of chemistry, metallurgy, and

biology. For this reason there will come more machines to handle advanced mathematics for the scientist. Some of them will be sufficiently bizarre to suit the most fastidious connoisseur of the present artifacts of civilization.

Thinking Machines.—The scientist, however, is not the only person who manipulates data and examines the world about him by the use of logical processes, although he sometimes preserves this appearance by adopting into the fold anyone who becomes logical, much in the manner in which a British labor leader is elevated to knighthood. Whenever logical processes of thought are employed—that is, whenever thought for a time runs along an accepted groove—there is an opportunity for the machine. Formal logic used to be a keen instrument in the hands of the teacher in his trying of students' souls. It is readily possible to construct a machine which will manipulate premises in accordance with formal logic, simply by the clever use of relay circuits. Put a set of premises into such a device and turn the crank, and it will readily pass out conclusion after conclusion, all in accordance with logical law, and with no more slips than would be expected of a keyboard adding machine.

Logic can become enormously difficult, and it would undoubtedly be well to produce more assurance in its use. The machines for higher analysis have usually been equation solvers. Ideas are beginning to appear for equation transformers, which will rearrange the relationship expressed by an equation in accordance with strict and rather advanced logic. Progress is inhibited by the exceedingly crude way in which mathematicians express their relationships. They employ a symbolism which grew like Topsy and has little consistency; a strange fact in that most logical field.

A new symbolism, probably positional, must apparently precede the reduction of mathematical transformations to machine processes. Then, on beyond the strict logic of the mathematician, lies the application of logic in everyday affairs. We may some day click off arguments on a machine with the same assurance that we now enter sales on a cash register. But the machine of logic will not look like a cash register, even of the streamlined model.

Selection Devices.—So much for the manipulation of ideas and their insertion into the record. Thus far we seem to be worse off than before—for we can enormously extend the record; yet even in its present bulk we can hardly consult it. This is a much larger matter than merely the extraction of data for the purposes of scientific research; it involves the entire process by which man profits by his inheritance of acquired knowledge. The prime action of use is selection, and here we are halting indeed. There may be millions of fine thoughts, and the account of the experience on which they are based, all encased within stone walls of acceptable architectural form; but if the scholar can get at only one a week by diligent search, his syntheses are not likely to keep up with the current scene.

Selection, in this broad sense, is a stone adze in the hands of a cabinetmaker. Yet, in a narrow sense and in other areas, something has already been done mechanically on selection. The personnel officer of a factory drops a stack of a few thousand employee cards into a selecting machine, sets a code in accordance with an established convention, and produces in a short time a list of all employees who live in Trenton and know Spanish. Even such devices are much too slow when it comes, for example, to matching a set of fingerprints with one of five million

on file. Selection devices of this sort will soon be speeded up from their present rate of reviewing data at a few hundred a minute. By the use of photocells and microfilm they will survey items at the rate of a thousand a second, and will print out duplicates of those selected.

This process, however, is simple selection: it proceeds by examining in turn every one of a large set of items, and by picking out those which have certain specified characteristics. There is another form of selection best illustrated by the automatic telephone exchange. You dial a number and the machine selects and connects just one of a million possible stations. It does not run over them all. It pays attention only to a class given by a first digit, then only to a subclass of this given by the second digit, and so on; and thus proceeds rapidly and almost unerringly to the selected station. It requires a few seconds to make the selection, although the process could be speeded up if increased speed were economically warranted. If necessary, it could be made extremely fast by substituting thermionic-tube switching for mechanical switching, so that the full selection could be made in one one-hundredth of a second. No one would wish to spend the money necessary to make this change in the telephone system, but the general idea is applicable elsewhere.

Take the prosaic problem of the great department store. Every time a charge sale is made, there are a number of things to be done. The inventory needs to be revised, the salesman needs to be given credit for the sale, the general accounts need an entry, and, most important, the customer needs to be charged. A central records device has been developed in which much of this work is done conveniently. The salesman places on a stand the customer's identification card, his own card, and the card taken from the article sold—all punched cards. When he pulls a lever, contacts are made through the holes, machinery at a central point makes the necessary computations and entries, and the proper receipt is printed for the salesman to pass to the customer.

But there may be ten thousand charge customers doing business with the store, and before the full operation can be completed someone has to select the right card and insert it at the central office. Now rapid selection can slide just the proper card into position in an instant or two, and return it afterward. Another difficulty occurs, however. Someone must read a total on the card, so that the machine can add its computed item to it. Conceivably the cards might be of the dry photography type I have described. Existing totals could then be read by photocell, and the new total entered by an electron beam.

The cards may be in miniature, so that they occupy little space. They must move quickly. They need not be transferred far, but merely into position so that the photocell and recorder can operate on them. Positional dots can enter the data. At the end of the month a machine can readily be made to read these and to print an ordinary bill. With tube selection, in which no mechanical parts are involved in the switches, little time need be occupied in bringing the correct card into use—a second should suffice for the entire operation. The whole record on the card may be made by magnetic dots on a steel sheet if desired, instead of dots to be observed optically, following the scheme by which Valdemar Poulsen long ago put speech on a magnetic wire. This method has the advantage of simplicity and ease of erasure. By using photography, however, one can arrange to project the record in enlarged form, and at a distance by using

the process common in television equipment.

One can consider rapid selection of this form, and distant projection for other purposes. To be able to key one sheet of a million before an operator in a second or two, with the possibility of then adding notes thereto, is suggestive in many ways. It might even be of use in libraries, but that is another story. At any rate, there are now some interesting combinations possible. One might, for example, speak to a microphone, in the manner described in connection with the speech-controlled typewriter, and thus make his selections. It would certainly beat the usual file clerk.

The "Memex"—a Machine Filer of Thoughts and Ideas.—The real heart of the matter of selection, however, goes deeper than a lag in the adoption of mechanisms by libraries, or a lack of development of devices for their use. Our ineptitude in getting at the record is largely caused by the artificiality of systems of indexing. When data of any sort are placed in storage, they are filed alphabetically or numerically, and information is found (when it is) by tracing it down from subclass to subclass. It can be in only one place, unless duplicates are used; one has to have rules as to which path will locate it, and the rules are cumbersome. Having found one item, moreover, one has to emerge from the system and re-enter on a new path.

The human mind does not work that way. It operates by association. With one item in its grasp, it snaps instantly to the next that is suggested by the association of thoughts, in accordance with some intricate web of trails carried by the cells of the brain. It has other characteristics, of course; trails that are not frequently followed are prone to fade, items are not fully permanent, memory is transitory. Yet the speed of action, the intricacy of trails, the detail of mental pictures, is awe-inspiring beyond all else in nature.

Man can not hope fully to duplicate this mental process artificially, but he certainly ought to be able to learn from it. In minor ways he may even improve, for his records have relative permanency. The first idea, however, to be drawn from the analogy concerns selection. Selection by association, rather than by indexing, may yet be mechanized. One can not hope thus to equal the speed and flexibility with which the mind follows an associative trail, but it should be possible to beat the mind decisively in regard to the permanence and clarity of the items resurrected from storage.

Consider a future device for individual use, which is a sort of mechanized private file and library. It needs a name, and, to coin one at random, "memex" will do. A memex is a device in which an individual stores all his books, records, and communications, and which is mechanized so that it may be consulted with exceeding speed and flexibility. It is an enlarged intimate supplement to his memory.

It consists of a desk, and while it can presumably be operated from a distance, it is primarily the piece of furniture at which he works. On the top are slanting translucent screens, on which material can be projected for convenient reading. There is a keyboard, and sets of buttons and levers. Otherwise it looks like an ordinary desk.

In one end is the stored material. The matter of bulk is well taken care of by improved microfilm. Only a small part of the interior of the memex is devoted to storage, the rest to mechanism.

Yet if the user inserted 5000 pages of material a day it would take him hundreds of years to fill the repository, so

he can be profligate and enter material freely.

Most of the memex contents are purchased on micro-film ready for insertion. Books of all sorts, pictures, current periodicals, newspapers, are thus obtained and dropped into place. Business correspondence takes the same path. And there is provision for direct entry. On the top of the memex is a transparent platen. On this are placed longhand notes, photographs, memoranda, all sorts of things. When one is in place, the depression of a lever causes it to be photographed onto the next blank space in a section of the memex film, dry photography being employed.

There is, of course, provision for consultation of the record by the usual scheme of indexing. If the user wishes to consult a certain book, he taps its code on the keyboard, and the title page of the book promptly appears before him, projected onto one of his viewing positions. Frequently-used codes are mnemonic, so that he seldom consults his code book; but when he does, a single tap of a key projects it for his use. Moreover, he has supplemental levers. On deflecting one of these levers to the right he runs through the book before him, each page in turn being projected at a speed which just allows a recognizing glance at each. If he deflects it further to the right, he steps through the book 10 pages at a time; still further at 100 pages at a time. Deflection to the left gives him the same control backwards.

A special button transfers him immediately to the first page of the index. Any given book of his library can thus be called up and consulted with far greater facility than if it were taken from a shelf. As he has several projection positions, he can leave one item in position while he calls up another. He can add marginal notes and comments, taking advantage of one possible type of dry photography, and it could even be arranged so that he can do this by a stylus scheme, such as is now employed in the telautograph seen in railroad waiting rooms, just as though he had the physical page before him.

Uses of the "Memex".—All this is conventional, except for the projection forward of present-day mechanisms and gadgetry. It affords an immediate step, however, to associative indexing, the basic idea of which is a provision whereby any item may be caused at will to select immediately and automatically another. This is the essential feature of the memex. The process of tying two items together is the important thing.

When the user is building a trail, he names it, inserts the name in his code book, and taps it out on his keyboard. Before him are the two items to be joined, projected onto adjacent viewing positions. At the bottom of each there are a number of blank code spaces, and a pointer is set to indicate one of these on each item. The user taps a single key, and the items are permanently joined. In each code space appears the code word. Out of view, but also in the code space, is inserted a set of dots for photocell viewing; and on each item these dots by their positions designate the index number of the other item.

Thereafter, at any time, when one of these items is in view, the other can be instantly recalled merely by tapping a button below the corresponding code space. Moreover, when numerous items have been thus joined together to form a trail, they can be reviewed in turn, rapidly or slowly, by deflecting a lever like that used for turning the pages of a book. It is exactly as though the physical items had been gathered together from widely separated sources and bound together to form a new book. It is more than this, for any item can be joined

into numerous trails.

The owner of the memex, let us say, is interested in the origin and properties of the bow and arrow. Specifically he is studying why the short Turkish bow was apparently superior to the English long bow in the skirmishes of the Crusades. He has dozens of possibly pertinent books and articles in his memex. First he runs through an encyclopaedia, finds an interesting but sketchy article, leaves it projected. Next, in a history, he finds another pertinent item, and ties the two together. Thus he goes, building a trail of many items. Occasionally he inserts a comment of his own, either linking it into the main trail or joining it by a side trail to a particular item. When it becomes evident that the elastic properties of available materials had a great deal to do with the bow, he branches off on a side trail which takes him through textbooks on elasticity and tables of physical constants. He inserts a page of longhand analysis of his own. Thus he builds a trail of his interest through the maze of materials available to him.

And his trails do not fade. Several years later, his talk with a friend turns to the queer ways in which a people resist innovations, even of vital interest. He has an example, in the fact that the outranged Europeans still failed to adopt the Turkish bow. In fact he has a trail on it. A touch brings up the code book. Tapping a few keys projects the head of the trail. A lever runs through it at will, stopping at interesting items, going off on side excursions. It is an interesting trail, pertinent to the discussion. So he sets a reproducer in action, photographs the whole trail out, and passes it to his friend for insertion in his own memex, there to be linked into the more general trail.

Wholly new forms of encyclopaedias will appear, ready-made with a mesh of associative trails running through them, ready to be dropped into the memex and there amplified. The lawyer has at his touch the associated opinions and decisions of his whole experience, and of the experience of friends and authorities. The patent attorney has on call the millions of issued patents, with familiar trails to every point of his client's interest. The physician, puzzled by a patient's reactions, strikes the trail established in studying an earlier similar case, and runs rapidly through analogous case histories, with side references to the classics for the pertinent anatomy and histology. The chemist, struggling with the synthesis of an organic compound, has all the chemical literature before him in his laboratory, with trails following the analogies of compounds, and side trails to their physical and chemical behavior.

The historian, with a vast chronological account of a people, parallels it with a skip trail which stops only on the salient items, and can follow at any time contemporary trails which lead him all over civilization at a particular epoch. There is a new profession of trail blazers, those who find delight in the task of establishing useful trails through the enormous mass of the common record. The inheritance from the master becomes, not only his additions to the world's record, but for his disciples the entire scaffolding by which they were erected.

Thus science may implement the ways in which man produces, stores, and consults the record of the race. It might be striking to outline the instrumentalities of the future more spectacularly, rather than to stick closely to methods and elements now known and undergoing rapid development, as has been done here. Technical diffi-

862 culties of all sorts have been ignored, certainly, but also ignored are means as yet unknown which may come any day to accelerate technical progress as violently as did the advent of the thermionic tube. In order that the picture may not be too commonplace, by reason of sticking to present-day patterns, it may be well to mention one such possibility, not to prophesy but merely to suggest, for prophecy based on extension of the known has substance, while prophecy founded on the unknown is only a doubly involved guess.

All our steps in creating or absorbing material of the record proceed through one of the senses—the tactile when we touch keys, the oral when we speak or listen, the visual when we read. Is it not possible that some day the path may be established more directly?

We know that when the eye sees, all the consequent information is transmitted to the brain by means of electrical vibrations in the channel of the optic nerve. This is an exact analogy with the electrical vibrations which occur in the cable of a television set: they convey the picture from the photocells which see it to the radio transmitter from which it is broadcast. We know further that if we can approach that cable with the proper instruments, we do not need to touch it; we can pick up those vibrations by electrical induction and thus discover and reproduce the scene which is being transmitted, just as a telephone wire may be tapped for its message.

The impulses which flow in the arm nerves of a typist convey to her fingers the translated information which reaches her eye or ear, in order that the fingers may be caused to strike the proper keys. Might not these currents be intercepted, either in the original form in which information is conveyed to the brain, or in the marvelously metamorphosed form in which they then proceed to the hand?

By bone conduction we already introduce sounds into the nerve channels of the deaf in order that they may hear. Is it not possible that we may learn to introduce them without the present cumbersomeness of first transforming electrical vibrations to mechanical ones, which the human mechanism promptly transforms back to the electrical form? With a couple of electrodes on the skull the encephalograph now produces pen-and-ink traces which bear some relation to the electrical phenomena going on in the

brain itself. True, the record is unintelligible, except as it points out certain gross malfunctioning of the cerebral mechanism; but who would now place bounds on where such a thing may lead?

In the outside world, all forms of intelligence, whether of sound or sight, have been reduced to the form of varying currents in an electric circuit in order that they may be transmitted. Inside the human frame exactly the same sort of process occurs. Must we always transform to mechanical movements in order to proceed from one electrical phenomenon to another? It is a suggestive thought, but it hardly warrants prediction without losing touch with reality and immediateness.

Presumably man's spirit should be elevated if he can better review his shady past and analyze more completely and objectively his present problems. He has built a civilization so complex that he needs to mechanize his records more fully if he is to push his experiment to its logical conclusion and not merely become bogged down part way there by overtaxing his limited memory. His excursions may be more enjoyable if he can reacquire the privilege of forgetting the manifold things he does not need to have immediately at hand, with some assurance that he can find them again if they prove important.

The applications of science have built man a well-supplied house, and are teaching him to live healthily therein. They have enabled him to throw masses of people against one another with cruel weapons. They may yet allow him truly to encompass the great record and to grow in the wisdom of race experience. He may perish in conflict before he learns to wield that record for his true good.

Yet, in the application of science to the needs and desires of man, it would seem to be a singularly unfortunate stage at which to terminate the process, or to lose hope as to the outcome.
